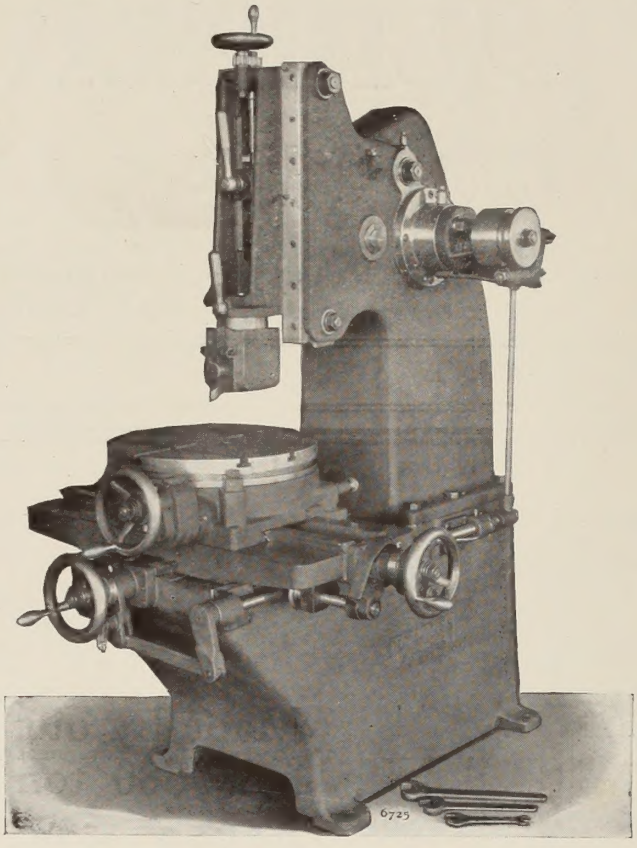
WELLAND - ONT.



The Pratt & Whitney New Vertical Shaper

Die Work Completed in One Setting.

A new machine, embodying features never before applied to a shaper. Especially adapted to machine concave, convex or irregular surfaces such as hexagons, irregular punches, dies, etc.

The swinging ram is a new feature permitting cuts to be taken on beveled work.

The tool head can be swiveled in the ram so that all four sizes of a piece can be finished in one setting without rotating the table.

Write for new illustrated circular "The Vertical Shaper."

An Exceptionally Powerful Drive

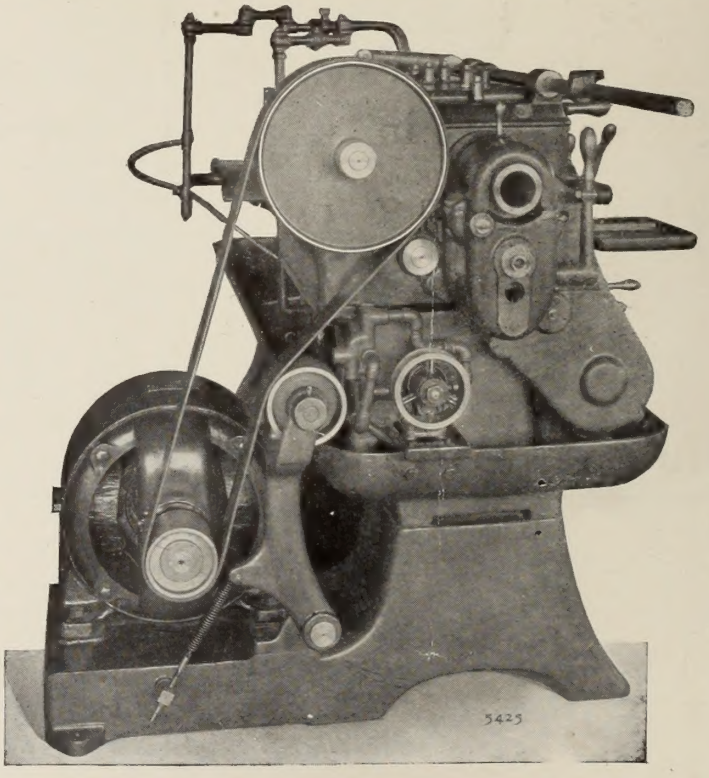
The Pratt & Whitney Turntable Lathe

Together with the great accuracy required for a Precision Turret Lathe, a rigid construction and a powerful drive are of the first importance. In fact, it is essential for a lathe that will work up to the limit of endurance of the new high speed steels.

A massive stationary head bolted solid to a heavy bed gives rigidity. The stationary head also makes possible as powerful a drive as desired. Head is of all geared construction entirely encased, the gears running partially submerged in oil. An easy running lathe diminishes the wear and preserves accuracy.

The Turntable is cross-feeding and is bound into position by a rigid binder at the head side of the Turntable, thus preventing lifting of the turret tool under heavy cut.

Fully described in catalogue "Turntable Lathe," sent on request.



Head End of Turntable Lathe, Showing Powerful Motor Drive

The
"Bemis & Call"
Combination Wrench

turns lost time through inconvenience into profits.

Without this Combination Wrench a mechanic's kit is incomplete. The "BEMIS & CALL" does the work better than two ordinary pipe and nut wrenches.

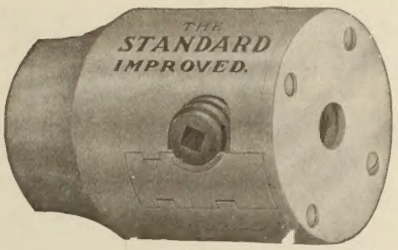
It must be a "BEMIS & CALL" to get quality.

This high grade Combination Wrench is made from carefully selected materials, and is thoroughly case hardened and finished by experts.

The Head Bar and Shank is a one piece forging. All parts are interchangeable

Write for our complete illustrated catalogue on wrenches—better do it now.

BEMIS & CALL HARDWARE AND TOOL CO.
SPRINGFIELD, MASS., U.S.A.



THIS IS THE STANDARD IMPROVED DRILL CHUCK

THIS chuck has no projecting jaws, and the face plate prevents the insertion of work larger than the chuck is designed to hold. Consequently, the jaws always remain true and never become bell-mouthed from undue strain.

The jaws and screws are of tool steel, carefully tempered, and the screws are larger than those of other chucks of similar size and type.

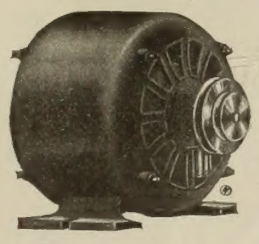
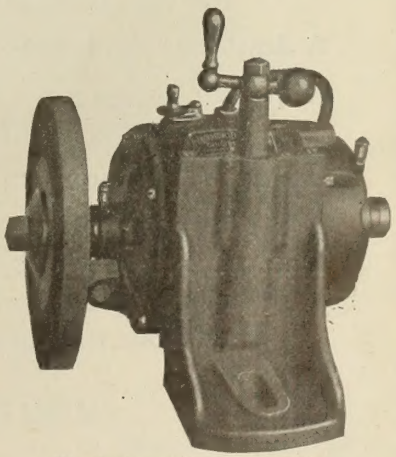
Westinghouse Small-Power Motors



The fact that the largest manufacturers of small motor-driven devices of all classes continue buying Westinghouse Small-Power Motors, year after year, stamps them as those giving satisfaction.

Care in the minutest detail of design, excellence of workmanship by the best labor and equipment obtainable; highest grade material best suited for small motor construction, are some of the reasons for their success in service.



Westinghouse Small-Power Motor Driving Bench Grinder.

Cost Reducing Features

An indestructible spindle bearing made of hardened steel and cast iron.

A head construction that gives more effective pulling power at the spindle than any other lathe built.

A patent "compensating V" that permits four times the bearing area between the carriage and bed found on other lathes.

A carriage in which the tool thrust is taken on a bearing the entire length of the carriage, and which positively will not climb the V.

A double-walled one-piece apron which will last as long as the rest of the lathe.

A quick change gear complete in one unit, giving thirty-six changes with two operating levers.

An offset compound rest which can be used without skinning the operator's knuckles.

The centres set back of the middle of the bed, giving greater swing over carriage and permitting the turning of work up to the maximum swing without the tool overhanging the bed.

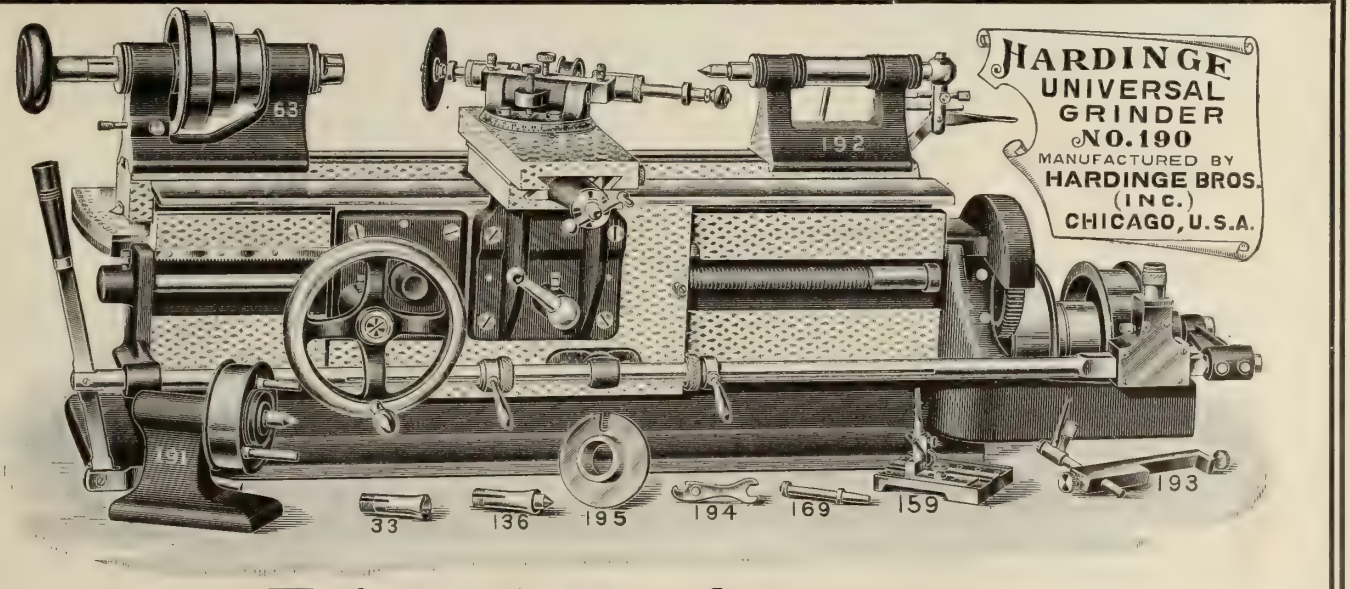
Canadian Agents: A. R. Williams Machinery Co., Toronto, and Williams & Wilson, Montreal



Think of the Advantage

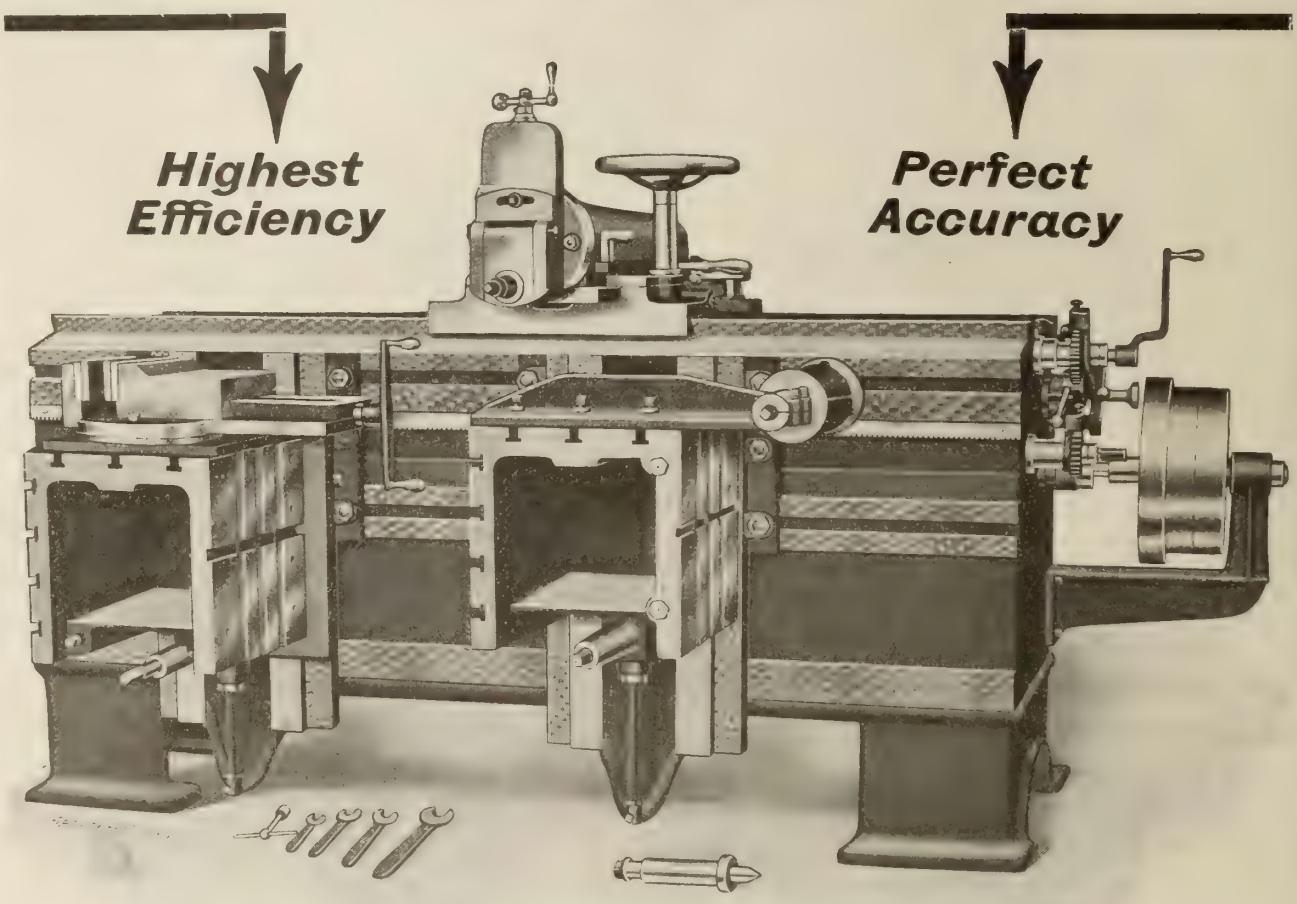
of being able to take that grinding job to a machine equipped with drawback chucks. Every tool room and manufacturing plant have felt the necessity of a grinder of this kind. Those taper reamers, milling cutters, hollow mills, in fact, grinding of any kind, may be accomplished, through the use of the Hardinge Universal Grinder, without spending more time to set up the job than it takes to do it.

The Hardinge is a truly Universal Machine, and you should write us to-day for further information.

ASK FOR SPECIAL CIRCULAR.

HARDINGE BROTHERS, Inc., 3135 Lincoln Ave., Chicago

Hendey Traverse Shaper
(20 x 60 Inch)



Stroke of Ram, 24 in.; Traverse on bed, 60 in., and will plane work 18 in. high. The stroke is fully adjusted while in motion, and can be changed at once to any required length and position without stopping. Tool slide has 6-in. travel and power down feed.

THE PATENT FRICTION CLUTCH DRIVING MECHANISM of this Shaper gives perfect accuracy of stroke, with the certainty of a crank machine, and in addition MAINTAINS UNIFORM CUTTING SPEED and POWER the entire length of stroke of Ram and gives quick return.

Has one Adjustable Table, which is pivoted on large Hinge pins in saddle, and can be tilted upwards to plane taper, the adjustment being accomplished by means of two screws at bottom of taper.

Furnished complete with Countershaft, Wrenches and improved Vise.

Approx. net weight N. O. S. 6,400 lbs. Immediate Delivery.

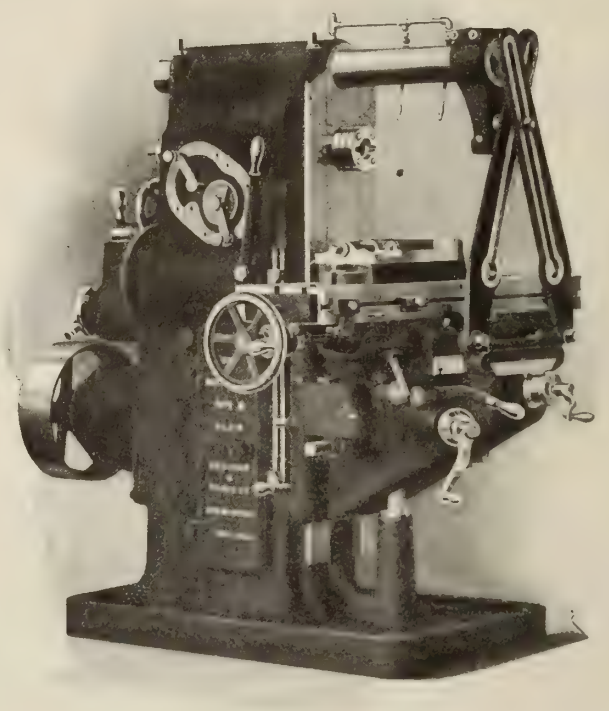
Canada Machinery Corporation, Limited

GALT, ONTARIO



CANADIAN MACHINERY READERS—

Gentlemen—

We take this opportunity for asking to be allowed to send copy of 1912 catalogue of Milwaukee Milling Machines, from which you will learn that we devote ourselves exclusively to the constant speed drive type of machine, having discontinued the cone pulley machine some years ago.

Sectional views are given, showing how the machines are automatically lubricated, the gears and bearings being constantly flooded with oil. The gears and most of the shafts are case hardened to prevent wear and increase their strength and stiffness.

Every machine is equipped with pump for lubricating the cutters, whether so ordered or not, means being provided for returning the lubricant from the work-table to the reservoir in the base of the machine that isfar superior to anything that could be done were these parts supplied as an extra attachment.

Cuts show clearly the self-contained means provided for reversing the spindle so that right or left hand cutters can be used and it is unnecessary to have direct and reverse countershafts, in fact no countershaft whatever is necessary, only belt direct to line shaft and no overhead belts.

Detailed views of the knee are given, this being a box section, closed on top, which adds immensely to the power and rigidity of the machine.

We can hardly point out to you in a letter of reasonable length the detailed advantages of our machines over those of other design, and that is why we ask permission to send our latest literature covering the constant speed type of millers. We are pioneers in the manufacture of this type of machine and have worked many years to perfect the minor details. Pages 6 to 23 inclusive are devoted to the subject of milling machine design, and if you will read this much carefully you will be able to say for yourself what is and what is not a good machine, as far as design is concerned, regardless of who makes it.

Thanking you for giving this your immediate attention, we are,

Very truly yours,

KEARNEY & TRECKER CO., Milwaukee, Wis.

The advertiser would like to know where you saw his advertisement—tell him.

COME AND SEE US IN OUR NEW PLANT

THE PLANT DRAWN TO AN EXACT SCALE

OUR new plant is only 40 minutes from the hotel district. It contains 275,000 square feet of floor space, exclusive of power house, which makes it the largest milling machine manufacturing plant in the world. The buildings have been planned for the most efficient handling and routing of materials, and provide ideal factory conditions as to lighting, heating and ventilation. Our equipment has been specially selected and tooled up for manufacturing in large quantities. Many important parts are made on machines designed especially for individual operations.

These things are not possible in the shop producing a smaller volume. They enable us to produce very much better machines and give you bigger value for the price.

We devote all our time and energy to the design and manufacture of Milling Machines and Milling Cutter Grinders. By this specialization and this concentration of effort on the part of a corps of men especially trained in this line of work, we are able to produce machines of the highest quality as to design, materials and workmanship.

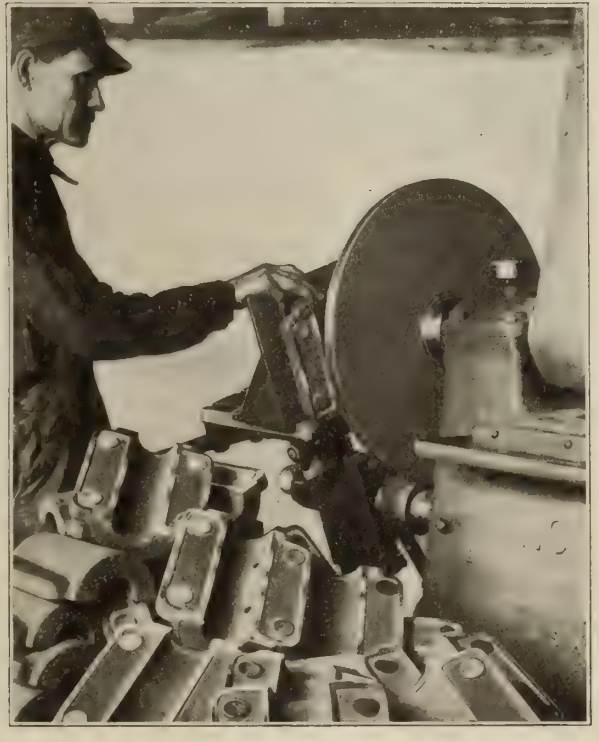
THE KEMPSMITH MFG. CO., Milwaukee, Wis.



10 per hour on Milling Machine

60 per hour on Gardner Grinder

READ THE DETAILS:

Here are a lot of cast iron Box Caps. It is required to face off straight and clean the under side of each piece. The greatest output that could be obtained from a $1600.00 Milling Machine was 10 pieces per hour.

Before testing these pieces on a Gardner Disc Grinder the pattern was changed so that a portion of the surface area to be finished was depressed below the finish line. (*Bring this point to the attention of your Designer*). Note here the saving in metal from the change more than paid for the grinding operation. These Box Caps are now being machined, right from the ROUGH CASTING, on a Gardner Grinder at the rate of 60 PER HOUR.

GET THIS INFORMATION

We prove to you beforehand a Gardner Disc Grinder will on suitable work increase your output 3 to 30 times, that its cost is less than one-fourth of your present equipment for the same work, that its upkeep is less. HOW? Simply send us a few unfinished pieces of your work. Our Experimental Department will test grind them, free of charge, and render detailed and guaranteed report of the test. We can also give close estimate from your blue prints or sketches.

We make the largest and most reliable line of Disc Grinding Machinery in the world. Our book of Disc Grinders will interest you.

You Can Double Your Output If You Install a

"SPRINGFIELD" Cabinet Turret Lathe

This is one of our latest productions and it contains several new features and improvements that ensure a maximum output at minimum cost. Its accuracy, speed and efficiency cannot be equalled.

The turret is so designed that one slight backward movement of the blades loosens the turret and at the same time withdraws the locking pin; a slight forward movement then produces the partial revolution of the turret for the next tool, and simultaneously locks and tightens it, the entire operation being done in a second or so by one hand.

This lathe is back geared, and has a four-step cone pulley of large diameter.

Do not hesitate. Write us at once for illustrated catalogue on our complete line of lathes and shapers. "SPRINGFIELD SERVICE" is guaranteed to save you money.

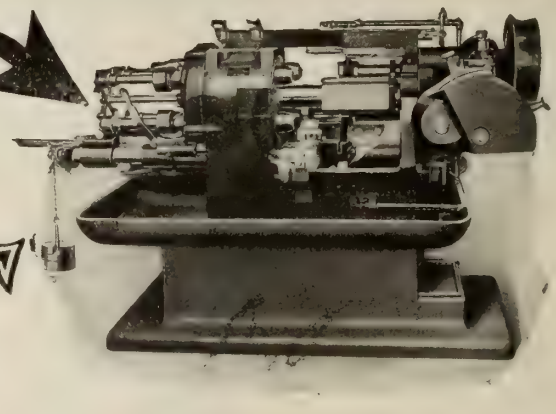
"The Turret Lathe that assures an Economical and Rapid Production."



"GRIDLEY" Multiple Spindle.

Gridley Automatics combine greater accuracy, a larger output and a wider range of work. Its past service has proved this to be a fact.

A Greater Output can be secured because the rigidity of the tools and general design of machines permit heavier cuts and coarser feeds to be maintained, and the type of cutting tool used has a longer life.

The Gridley Automatic

With this machine in your shop you will save much time and money, as one operator can attend to several machines at once, and can use tools tandem, thereby increasing production at minimum labor cost. We manufacture both Multiple Spindle and Single Spindle Automatics.

Communicate with us at once and get full particulars regarding "Gridley Service."

—all these SHELBY SEAMLESS STEEL TUBES, drawn cold, through dies, like a piece of wire. Notice the smooth little round ones, the sturdy big ones; the thick and the thin ones, as well as the squares, rectangles, hexagons, ovals and odd shapes; then think how much time, how much temper, and how much REAL MONEY you could save by the use of this excellent material instead of machined steel, or cast iron, or brass.

Fifteen years ago you couldn't buy these tubes, because we didn't know how to make them. Now we will furnish you any size from ⅛ to 5½ inches outside diameter, and practically any thickness, from

Our Montreal or Toronto Stocks

and larger sizes up to 20 inches, on special orders. We have tubing with walls as thin as a business card, some so thick there's hardly room for a hole. We have tubing made from mild steel, and annealed for any particular purpose; also high carbon steel for bushings and special tensile requirements. We sell tubing from 3½ per cent. Nickel Steel for automobile construction. In a word, if there's *anything* you want in steel tubing, we have it, or can get it.

Look at the picture, which shows only a few of the sizes and shapes we carry, think how you could use Seamless Tubing in your work, then send for the story of how SHELBY TUBING is made. There are more possibilities for the use of this tubing than we could tell in a book. Write us—we will be glad to answer your questions.

High Speed Steel Has a Solid Foundation In a Name That Means Something

Cutting speed attained on cast iron: Roughing cut, 140 ft. per minute—finishing cut, 210 ft. per minute.

In NOVO SUPERIOR you secure a materially increased speed over the high speed steels now in use, the highest quality, greatest toughness, longest life (3 times that of any other) and exceptional ability to cut very hard materials. The cutting edge retains its sharpness from 3 to 4 times longer than other high speed steels. Hardens in oil, air or water, and is now carried in stock in our warehouse in all current sizes, flat, squares and rounds; annealed and unannealed.

Why Didn't We Protect Those Windows, too, With Fenestra Sash ?

What *water-tightness* is to an ocean liner—
What *burglar-proofness* is to a bank—
What *strength* is to a sky-scraper—
Fireproofness is to a modern industrial building.

It would seem hardly less logical to handicap the watertight compartments of a ship with frail partitions, to offset the 3-foot cement floors of a vault with a wooden trap-door, or to construct a Singer building on a doubtful footing, than it is to build a modern factory of fire-proof construction, equip it with sprinkler-systems, fire-doors and fire-alarms, and then to demoralize the whole chain of expensive and otherwise carefully planned fire-protection by tolerating the weak link of wooden sash.

Scientific factory construction relegates wooden sash to the day of clapboard walls, plank floors and shingle roofs.

Where else can you reasonably class them ?

FENESTRA FIRE PROOF SASH

glazed with ordinary wired glass is positively the last word in fire-resistance as applied to windows.

Common sense dictates that.

Actual fires have proven it beyond question. In a fire at Stoneham, Mass., in September, a building equipped with FENESTRA SASH was practically surrounded by a burning varnish factory. Reglazed after the fire, the Sash were as good as new. Photographs on request.

Remember, too, that FENESTRA SASH also *light* and *ventilate* a building better than any others. They're made to suit individual needs.

If you are interested in the planning or construction of a building where *light*, *fresh air*, and *fire protection* are essentials, let us send you our "Fenestra" Catalog.

STEEL AND RADIATION, LIMITED

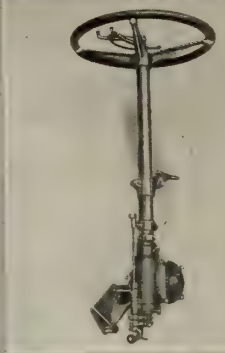
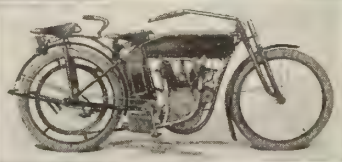
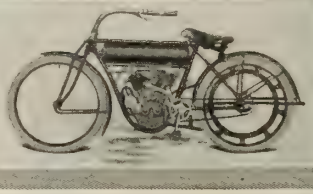
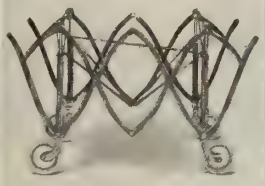
The POWER of SUGGESTION









IT was a very ordinary old kettle containing very ordinary water that suggested to Watt the power of steam.

Occasionally a manufacturer like Watt makes note of the possibilities of ordinary things when adapted to new purposes.

Steel tubing is a very common article in the industrial world. To the usual type of man it suggests nothing, but to the other type, and there are many of him, it may bring to mind a hundred ways to improve various articles.

The articles shown in this advertisement, together with hundreds of entirely different others, are being made of

"STANDARD" SEAMLESS STEEL TUBING

Isn't there some way that you can employ it?

Standard tubing is light, strong, ductile, and it takes a beautiful finish. We can bend it into any shape you desire and its cost is never prohibitive.

Rot-Proof Air Hose for Use and Abuse

You save money when you buy Goodyear Air Hose for the reason that it lasts longer—gives more service than any other air hose manufactured. This is because we make it by a special process that renders it impervious to the attack of compressor oil—the ruinous agency that rots all other air tubes.

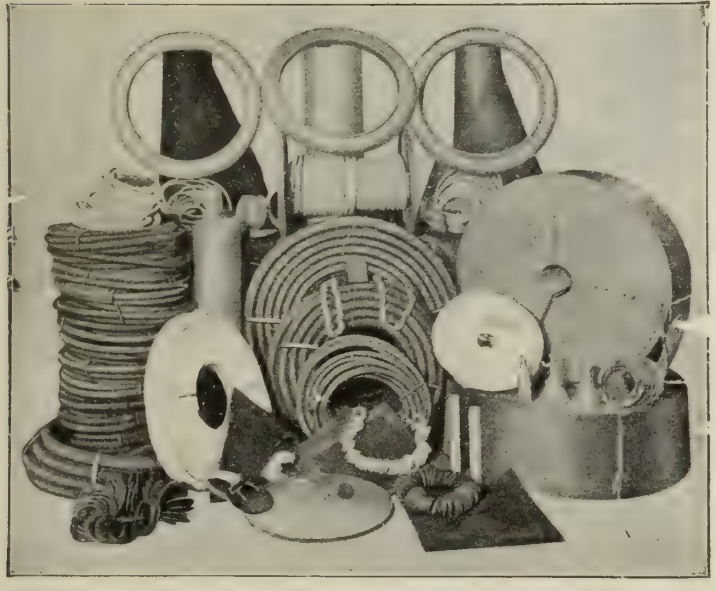
GOODYEAR

Air Hose

The Economical Hose for all Pneumatic Uses

The great difficulty with all rubber air hose is that due to the action of the oil that comes from the compressor. This oil rots the inside of the tube. Then it chips off, clogs up the throttle and before you know it your tube is useless and your tools need repairs.

All this is now overcome. After long and costly experimenting our experts have now perfected a tube made of a special compound that resists oil and the heat developed by air compression. It neither chips, hardens nor cracks. And when other hose begins to *play out*, this hose is as *good as new*.



A Few of the Lines We Manufacture

Goodyear Air Hose is further protected from cuts and bruises by a heavy canvas jacket. This brings an extra thick ply of rubber between outer canvas cover and first inner layer of fabric, resulting in a hose of unequalled strength and toughness.

Can be supplied with the further protection of wire winding or Marlin wind. Made in three grades. Used in practically all mining operations, steel construction works and boiler works—wherever pneumatic tools are in use.

Write to-night for catalog and prices.

SAVES OIL

THE WRITER OF THE FOLLOWING LETTER knows that every time an oil is used over again it loses some of its lubricating qualities, until finally it is entirely unfit for use.

We are trying to show Magnolia from a different view point in each monthly issue of our advertisements.

We have shown the WATER TEST by the U.S. Government; we also recently published a letter showing that Magnolia had been running sixteen years in a shaft bearing and of that time it HAS RUN SIX YEARS WITHOUT A DROP OF LUBRICATION, and it is still running.

We are able now to present a letter of recent date, showing that the use of Magnolia effected a saving in oil of from one-third to one-half, and we have quite a number of similar testimonials:—

MAGNOLIA METAL CO. New Athens, Ill., Sept. 17, 1911

Gentlemen—I have used Magnolia Metal for a good many years, and I have never had a hot box or bearing, and can say that it will outlast any other metal on the market to-day.

I have used from ONE-THIRD TO ONE-HALF LESS OIL where the Magnolia Metal has been used. I have USED THE OIL OVER AND OVER AGAIN until it has been all used, without the least heating of bearing. I can safely recommend Magnolia Metal to all engineers as the best and cheapest metal to use.

Respectfully, JOHN J. JOHNSON, Engineer.

Buffalo "B" Volume Exhausters

have a decided advantage over the usual type in the solid, one-piece peripheral shell.

Not only is this construction very rugged and strong, but the absence of joints under pressure in the shell prevents leakage of air and waste of power. The blast wheel is strongly built, accurately balanced, and, together with the extra long oil-ring bearings insures smooth, easy and quiet operation.

BUFFALO EXHAUSTERS are especially adapted for handling dust and refuse from emery and buffing wheels and tumbling barrels; and smoke, gases and fumes generally. You can always depend on efficient, reliable operation.

A wide range of sizes and capacities make it easy for you to select just the one for your requirements. Ask for catalog 178-LD and prices.

RENOLD PATENT SILENT CHAINS

What Users Think

Montreal, Feb. 8, 1909

Messrs. Jones & Glassco, Montreal

RE RENOLD SILENT CHAIN DRIVE.

GENTLEMEN,—In reply to your inquiry of Jan. 30th, I may say that the Renold Silent Chain Drives we have installed are giving every satisfaction.

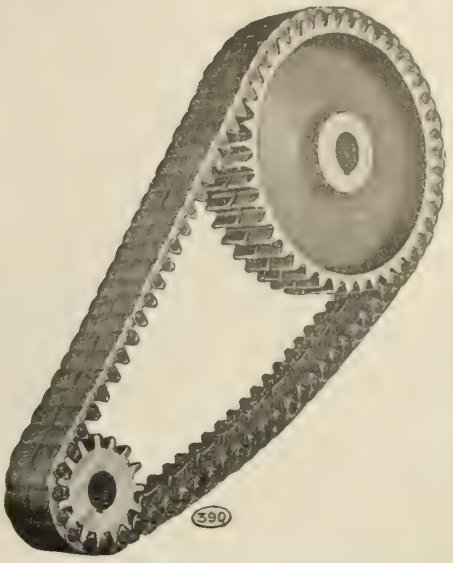
Our first drive was installed to replace a 12 in. belt which was giving us trouble on account of short centres: this chain has run continuously for four years without the slightest trouble.

Our second drive was installed on a mixing machine doing heavy duty and which had previously broken up two sets of spur gearing, this chain has run over three years with no sign of wear yet.

Our third drive was installed on a calendering machine after breaking two sets of helical gears, and this has been so successful that we are now installing two more similar drives.

I would be perfectly willing to make an appointment with any person genuinely interested and show him the drive in operation.

The above comes from one of the largest manufacturers in Montreal and is signed by the Mechanical Superintendent. Up to the present (1911) these drives have not received repairs of any kind.



Write for Catalogue

So satisfactory has their experience been that they are ordering (for a new extension) Renold Chain Drives throughout.

"Throw that noisy gear away, Jim, I'm putting on a NEW PROCESS"

Both men and machines are benefited by New Process Noiseless Pinions. Efficiency of workmen is dependent upon their willingness as well as ability, and willingness is influenced immensely by surroundings. Men who work endure noise because they have to, not because they like it, for noise hinders honest effort, and is a positive menace to health.

The best way to relieve mental fatigue and nervousness from this source is to substitute New Process Noiseless Pinions for the metal ones on the noisy drives.

There are much more important advantages attendant to the use of New Process Pinions than merely killing noise. Our book "Noiseless Gear Driving" explains this in detail and is well worth a careful reading. You can have a copy for the asking, and also the advice of our engineers if you will state the conditions for which you are figuring on noiseless pinions. 41

PUMPS

The superior excellence and splendid results shown by

"FAIRBANKS-MORSE"

pumping machinery are largely due to the fact that for many years we have manufactured Hydraulic Machinery of all descriptions. We are therefore able to build pumps which are properly designed and adapted to every-day use. This is of the greatest importance in a first-class pump, for the usefulness of an engine may be lost if the pumping machine is badly designed.

You will get all these important features when you purchase a "FAIRBANKS-MORSE" pump.

Let us solve your pump problems.

Double-Cutting and High Speed Planing Machines *

By J. Hartley Wicksteed **

The writer makes a strong plea for the elimination, to the fullest extent possible, of the idle return stroke, and shows that such advantages as reduced wear of tools per unit of surface planed, increased quality of product and larger output are now available through the utilization of proper drive mechanisms and equipment.

THE Planing Machine with its idle return-stroke is necessarily inferior in principle, for the economical removal of material, to a lathe with its continuous-cutting action; nevertheless, plain surfaces are best done on planing machines. The problem of minimising the time spent on the idle return-stroke has naturally received great attention, with the result that, in some cases, it has been reduced to one-tenth of that consumed in the complete cycle of the table; but, why do we not eliminate the idle stroke altogether, and make the machine cut equally on both the forward and backward strokes? It is hoped that, in the following paper, the conditions will be explained under which this is undoubtedly the most economical method, and also the conditions under which single-stroke cutting should be preferred.

Change-speed Reversing Motors.

The recent development of change-speed reversing motors has overcome the chief objection to an extended use of the double-cutting principle. With an equal speed to the planing-machine table on both the forward and backward cut, it followed that, when the work did not permit of the use of both tools, due to want of clearance at the end of the stroke, as, when planing in a steam-chest, the absence of a quick return-motion on the idle stroke discounted the advantages gained on other work where double cutting could be employed. With the variable-speed reversing motor, the drive can now be set either to reverse at equal speeds for double cutting, or to drive slowly on one stroke and quickly on the other, when necessary to plane only in one direction. Thus, in the machine illustrated by fig. 1, the table is driven at speeds varying between 20 and 60 feet per minute, on either stroke. The motor is regulated by varying the field strength, and will stand heavier intermittent loading at the lower speeds than at the higher; hence, it will exert the full horse-power at all speeds, the torque on the motor-shaft being approximately inversely proportional to the speed. Again, the slower the speed at which the table is driven, the heavier is the cut that can be taken. In general, the machine cuts on both strokes, but the double-cutting tool-holder can be removed and a strong single tool-holder substituted, capable of carrying a long projecting toolstock for heavy cuts on steel, in cases where the work does not lend itself to double cutting.

Double Cutting on Cast Iron.

In planing cast-iron, the advantages of double-cutting are twofold, for, besides having two feeds to the tool-box on each cycle of the table, the back-to-back tools mutually assist each other by chipping away the scale in front of them in either direction, so that each tool has clean metal to enter at all the edges of the casting with which it comes in contact. The tools are thus saved from so much wear that, instead of two tools requiring more fixing, they require, on the whole, less than does a single tool; the reason being that the back-to-back tools so save each other from wear that they do not need to be removed and re-fixed during the progress of the work, for the purpose of re-grinding. Again, the first roughing cut is more uniform if made with two tools, because they get so much less worn between the first cut and the last, partly because each tool only takes alternate cuts, thus reducing the wear to half what a single tool would be subjected to on one job and with one setting, and further, because of the assistance which each tool has rendered to its companion in preparing clean metal at all the edges where the single tool would have had to face hard scale.

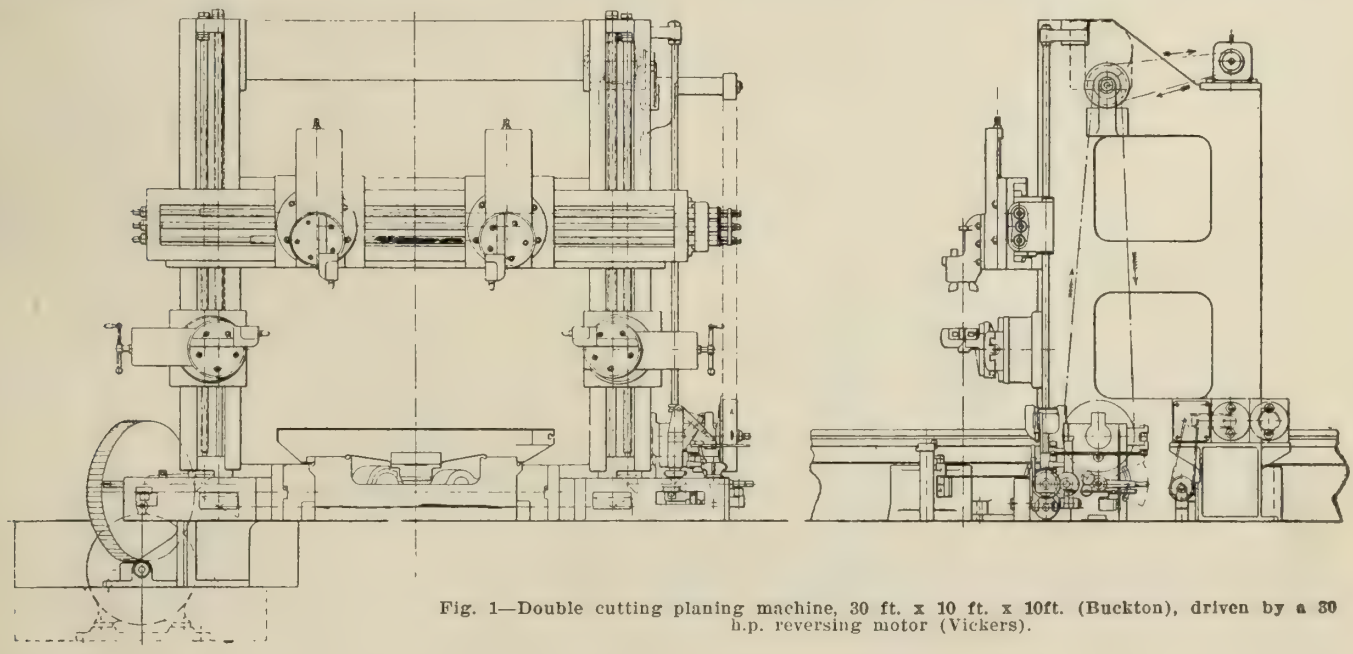

Fig. 1—Double cutting planing machine, 30 ft. x 10 ft. x 10ft. (Buckton), driven by a 30 h.p. reversing motor (Vickers).

*Abstract of paper read before the Institution of Mechanical Engineers (Eng.), Nov. 17, 1911.

**Past President, Leeds, England.

It has been found that turbine casings, for example, could be planed true in less time by double than by single cutting, even if the time taken by the idle return-stroke were eliminated altogether. The reverse position of the back tool also makes it particularly advantageous for taking broad finishing cuts; it does not require cranking back to prevent making chatter marks, because it has no tendency to dig into the work. For the same reason it can be advantageously used for cutting grooves with a parting tool. In these cases, although the double-cutting tool-holders are not changed, the back tool only is inserted and the back stroke can be driven at 20 feet per minute, with an idle stroke, on the usual forward stroke, of 60 feet per minute. There are also occasions where it saves turning the work round end for end to have a tool available for planing up to an obstruction in either direction.

Feed of Tool Boxes.

The feed of the tool-boxes is effected by a continuous running belt-pulley and a friction-clutch, which is thrown in at each reversal of the machine, and permits the belt-pulley to take one, two, or four complete revolutions before it is thrown out. Further changes of feed are provided in a gear-box. If one tool alone is in action, the tappet at one end of the table is turned back so that the feed does not operate on that reversal. The manner of double-cutting is to fix both tools precisely back to back; in fact, the second tool is adjusted by simply dropping it into the furrow made by the first tool. The back tool follows in this furrow until the end of the stroke, when it receives a feed motion. It then cuts a further furrow in which its companion follows free, and thus, on a single cycle of the table, two furrows have been cut of equal width and equal depth. Assuming a feed of $\frac{1}{8}$ inch at each reversal, then, at the completion of the cycle, $\frac{1}{4}$ inch would have been traversed. Fig. 2 shows a constant-speed double-cutting planer driven from a line-shaft. It planes 36 feet long by 8 feet square.

It is astonishing to the author to see any machines put down for the express purpose of planing engine base-plates, machine-beds, table, or tank-plates, with an idle return-stroke even if provided with gang tools, when two back-to-back tools would do all such work with much greater economy in the wear of the cut-

ting tools, the wear and tear of the machine, the cost of driving power, the time of doing the work, and the quality of the work done.

Advantageous Single Cutting Conditions

It must be conceded, however, that for work of great variety, and in some cases for special work, the bulk of which may only lend itself conveniently for cutting in one direction, the saving of as much time as possible on the idle stroke is very advantageous. For instance, in planing railway switches, with heavy cuts on very hard steel, it would be dangerous to enter a tool in the direction of facing the point, consequently, this special work is done cutting on one stroke, and the quickest possible idle-return. In miscellaneous work, also, fixed to the table by cramps and bolts which may interfere with the 6-inch over-run of the back-to-back tools, there are advantages in cutting in one direction only. As a consequence, on machines of moderate size, where practicable to get a quick return of about 8 to 1, it is hardly worth while to have a double equipment of tools and tool-holders, especially, as, on short jobs requiring right and left-hand tools for planing down vertical faces, or for undercutting, or for rounding the corners of the work, the single-cutting tool-box would be almost constantly in use.

Various Types of Machines.

Fig. 3 shows a machine with tandem tables, each of which will separately plane 16 feet long by 5 feet wide by 5 feet high. It will cut at any speed from 17 feet per minute to 60 feet per minute, and return at 136 feet per minute. It is driven by a 50-b.h.p. electrical set made by the Lancashire Dynamo and Motor Co. The motor generator is placed upon the top of the machine and runs at a constant speed. The motor is driven from the mains and can be either alternating or direct current. The generator supplies current to the planer motor, the voltage of which is varied, thus giving changes of speed on the machine over a total range of 8 to 1. The machine will take the same strength of cuts at any speed from 17 feet to 60 feet per minute, the horse-power given out by the planer motor being directly proportional to the cutting speed.

The next machine to be described is of exactly the same strength as the foregoing. It gives the same weight of cut at slow speeds and has the same ratio of quick return; but, instead of being driven and reversed by a reversing motor, it is driven either by a belt from the line-shaft or by a continuous-running motor. Fig. 4 shows the machine, to plane 16 feet by 5 feet by 5 feet, driven by a 30-h.p. motor running at 600 revolutions per minute, the power being delivered through belts to the machine. The belts do not shift on fast-and-loose pulleys but are themselves tightened and loosened alternatively, and at half stroke of the jockey-pulleys, each runs loosely in a loop under its respective pulley without touching it. The cutting speeds are 17, 35, and 60 feet per minute, and the return speed 136 feet per minute. The machine has a self-contained countershaft, which may be belt or motor-driven, and two open belts, as has been said, to convey the reverse motions to the cutting and return strokes. One belt for the quick return is driven from the countershaft or motor-spindle, the other belt for the variable cutting-stroke is driven through a three-speed gear-box. The gear-wheels run in oil and only one pair is in mesh at a time, namely, the pair giving the speed required for the cut in use. On account of the drum of this belt being driven through single-purchase gearing it runs in a contrary direction to the quick-speed belt, and, therefore, reverses the machine without being crossed, which enables it to drop plumb round its pulley. Each belt encloses a jockey-pulley. The pedestals for the jockey-pulleys are adjustable, so that a good endless belt never requires taking up and joining. Both jockey-pulleys are thrown from the same rocking shaft, and when the reversing gear rocks this shaft in one direction, the driving-belt is tightened by its jockey-pulley, and when it rocks in the contrary direction, the driving-belt

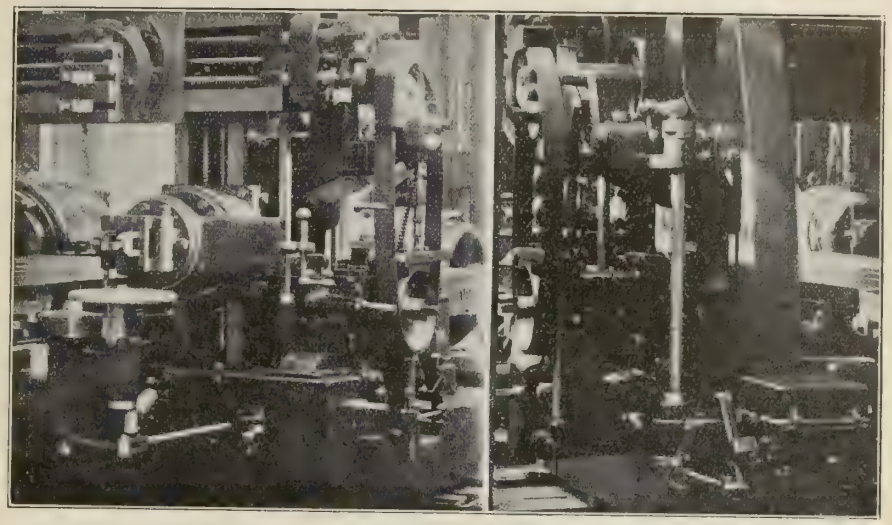

Fig. 5 Mechanism for feeding and traversing the tool boxes and for raising the cross-slide on large planing machines (Buckton).

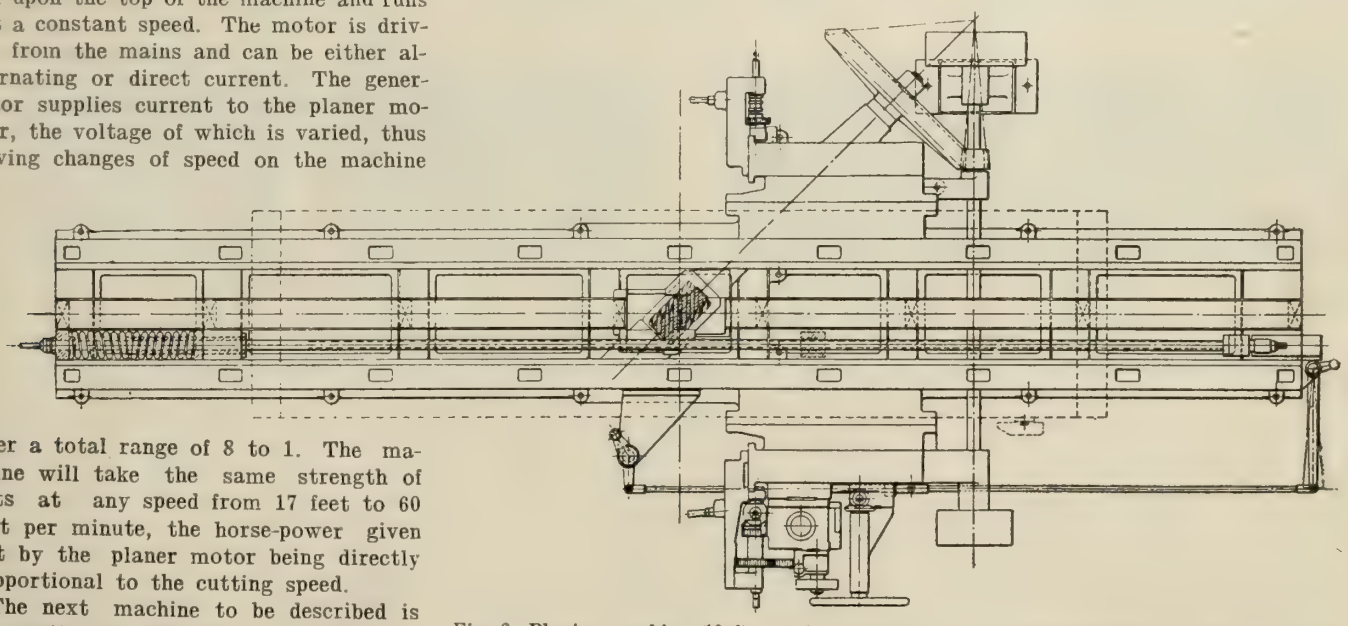

Fig. 6—Planing machine, 16 ft. x 5 ft. x 5 ft. (Buckton), showing reaction spring for high speed return stroke.

is loosened and the quick-return belt is tightened. The belts are endless belts from the makers' works without any laced joints or metallic joints, and any stretch that ensues in a new belt is taken up by moving the position of the jockey-pulley. The grip of these open belts is so smooth upon their pulleys that there is not the slightest knocking on the gearing, at reversals, of the machine. They themselves form a most perfect friction brake drive, and no cushioning device or friction coupling is required. The belts are 8 inches wide, and, as they are not subject to contrary flexure round the jockey-pulleys, and encounter no edge friction from belt striking fork, they are exempt from the elements of self-destruction usually found in heavy planing-machine belts.

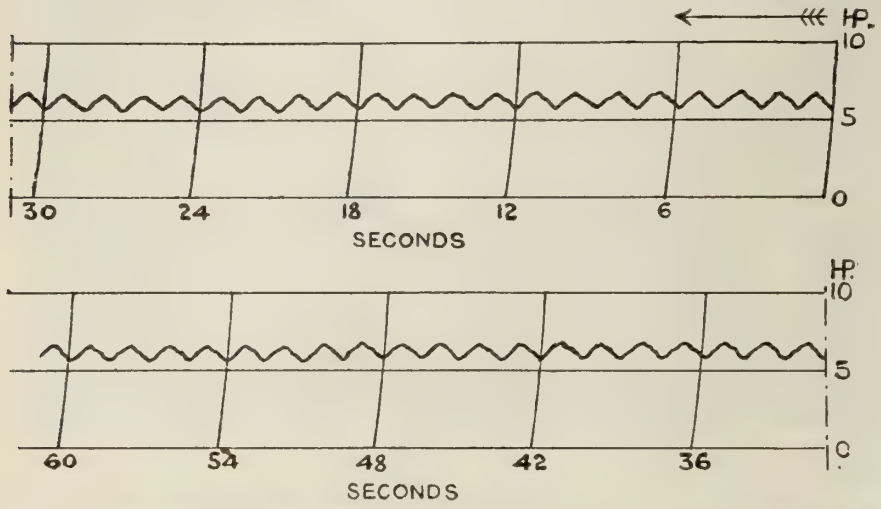

Fig. 9—Power diagram from planing machine, 10 ft. x 4 ft. x 4 ft. (Buckton), 40 cycles per minute.

Belt-driven Planers.

It is, perhaps, needless to say that the chief inertia in stopping or starting a belt-driven planer resides in the rim of the driving pulley. During the quick return-stroke, the shaft of this pulley makes about 800 revolutions per minute, and it is obvious that if this shaft be driven by a pulley 24 inches diameter with 8 inches face, instead of a pulley 48 inches diameter with 4 inches face, the weights of the pulley-rims would be about the same, but the peripheral speed of the one would be twice that of the other, and the inertia to contend with in the larger diameter pulley would be four times that in the smaller diameter pulley, although the belt driving power would be the same. Therefore, by using broad belts of low velocity instead of narrow belts of high velocity to deliver the power of the motor on to the cut, the chief inertia has already been reduced enough to enable the return speed to be doubled without increasing the inertia of the pulley-rim. Incidentally the broad slow belt is a better brake than the quick narrow belt an account of its broad surface and low velocity.

The author does not claim to have discovered the advantages of the broad slow belt for reversing pulleys. That principle was first introduced by Mr. W. C. Mitchell, and has been applied by him to many heavy planing machines. His system is that of tightening and loosening belts by jockey-pulleys acting upon the outside of the belts, and the chief difference in the author's system is that the jockey-pulleys act upon the inside of the belts and that the rocking shaft which works them is rocked from a crank-pin semi-revolving, so as to reach opposite dead centres at each reversal.

Inside Tightened Loose Belt Applied to Feed Motion.

The same system of a loose belt tightened from the inside is also applied to the feed motion. When the handle, Fig. 5, of its jockey-pulley frame is lifted, the feed motion runs continuously for traversing the tool-boxes and for raising the cross-slide. When the handle is dropped, the continuous motion ceases, but when the machine is running, a lever, from the rocking shaft which throws the main jockey-pulleys, pulls a pawl lever engaging into the frame of the feed-motion jockey-pulley, and thereby tightens the feed belt, just at the end of the quick-return stroke. As soon as this tightened belt has driven the first motion of the feed gear one revolution, it has also turned a stripping disc $\frac{1}{4}$ of a revolution, stripped the pawl out of engagement, and allowed the handle to drop, loosening the belt, and, at the same time, pressing a brake upon the feed-pulley to prevent over-run, and has given a feed of 1-32 inch. The stripping disc has four wipers, which, when all are in operation, strip the jockey-pulley after the first motion feed-wheel has made one revolution.

The wipers can be turned down, and, when only two are left in action, the feed-pulley receives two revolutions before the pawl is lifted, and the feed becomes 1-16 inch. When only one is left, the feed-pulley receives four revolutions before the pawl is lifted, and the feed becomes $\frac{1}{8}$ inch. The first motion feed-pulley drives through two change-gearings, and when the quicker gear is thrown in, the feeds obtained from the stripper plate become $\frac{1}{4}$ inch, $\frac{1}{2}$ inch, and 1 inch. By this simple automatic gear, therefore, six rates of feed are obtained varying from 1-32 inch to 1 inch.

The tool-boxes can be traversed without altering any clutches. For example, assuming that a feed is operating upon one of the tool-boxes, and, in order to pass over a part which does not require planing, it has to be traversed 12 inches to come up to its fresh cut, then, without making any change in the feed-gear, and by simply holding the jockey-pulley into the belt by its hand-lever, the motion becomes continuous instead of intermittent. The moment the hand-lever is dropped, the intermittent feed-motion is resumed. The direction of traverse is reversible by a handle. All

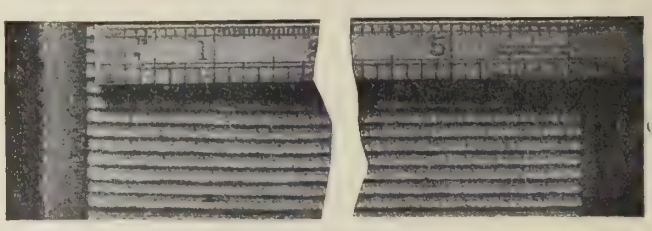

Fig. 8—40 cutting cycles per minute, with table reversing 80 times per minute. Length of stroke, 6 inches. Between landings, ⅜-inch and ⅛-inch wide

SPECIMENS OF WORK FROM SPRING-BALANCED PLANERS (BUCKTON).

the feed-motions and the traversing motions of the tool-boxes and the raising and lowering of the cross-slide are effected by power from this same continuous running belt. The table is driven through a rack by Sellers' spiral gearing. The guides of the table and bed are flat horizontally and slightly undercut at the sides. The table therefore cannot lift under any circumstances.

Reaction Spring Equipment.

The plan view of this machine, Fig. 6, shows the arrangement of a reaction spring placed in the bed of the planing machine, which enables it to attain the speed named without distress upon the return belt or overload upon the prime mover. It will be seen from the drawing that there is a boss cast on the second cross-bar at the front end of the bed, and abutting against this boss is a spiral spring about 2 feet long. Through this spring, a screw-shaft is passed, carrying a collar to press against the outer end of the spring, and also carrying a heavy nut against which a lug, cast solid under the table, impinges. By turning the screw-shaft, the nut can be traversed over a length of 16 feet into any position desired for the reversal of stroke. When the lug under the table impinges upon its nut, it moves the screw-shaft endways, and by the collar at one end compresses its spring. On one end of the screw-shaft a cam-plate is carried on a crosshead, and the end movement of the screw, carrying the cam-plate with it, moves the lever of the belt striking gear, and thus the same movement of the screw-shaft compresses the reaction spring and reverses the drive. The synchronism of these two operations is not disturbed by turning the screw round and altering the position of the nut to adjust the length of stroke, and this can be done even while the machine is in motion. The place, at which the table ends the cutting stroke, always corresponds with the position of the nut, namely, anywhere over the 16-feet range of the screw-shaft. The screw is 1 inch pitch, which is convenient when the operator is setting the stroke for exact clearance, as each full revolution of the screw alters it a known inch. The screws can be turned by hand so rapidly that an adjustment over a range of 10 feet can be effected in 1 minute. At the end of the screw-shaft, passing through the spring where the cam-plate is placed for reversing the table from the cutting to the idle stroke, it will be seen that there is a little space between the cam-plate and the belt striking lever. This is to give a late cut-off to the belt striking gear so as to prevent the driving belt being loosened before the spring is sufficiently compressed. While the cam-plate is passing through this space on the 60-feet cutting stroke it is compressing the spring, wholly by the residual energy of the moving masses, and when the space is covered and the lever kicked, the spring has made a dead beat of 4 inches.

The scale of this spring is 1 ton per inch, giving a terminal pressure of 4 tons. Thus, at the end of each cutting stroke, the spring being compressed 4 inches, there is, at the moment of the table reversing, such a thrust upon it as will help to start it on its quick-return journey. The quick-return belt is thereby greatly relieved, as it is not called upon first to take out the kinetic energy of the table and the revolving pulleys in one direction, and then to supply a further amount of energy to accelerate them in a contrary direction, but, instead of this, the whole of the residual energies of the revolving parts and of the moving table at the end of the cutting stroke are stored up in the spring, and are immediately returned by its reaction, to assist in starting up the quick-return stroke.

When the speed of cutting stroke is 60 feet per minute, more than the necessary amount of work is supplied to compress the spring by the kinetic energy of the moving parts, but when the table is driven at its slowest speed of 17 feet per minute a little assistance is required from the drive at the end of the cutting stroke to complete the compression of the spring. Seeing, however, that the drive is from a constant-speed motor and acts through $3\frac{1}{2}$ times the multiplying power of gear when the cutting speed is at its slowest, it happens that at the very time when there is a deficiency of energy in the moving parts for the complete compression of this spring, there is a surplus of power in the drive, beyond what is required to complete the maximum cut, without putting any overload upon the motor. By the reaction of the spring described, the table has a good send-off at the beginning of the quick return-stroke, and no dwell is perceptible at the point of reversal; there is no shock on the gearing, and the curve of the power diagram does not rise above the full-load line.

Spring Action Effects.

The following detailed description will explain the action of the spring. The table, when ready for starting its return stroke, is under the influence of a spring compressed to a load of 4 tons and stored with 8 inch-tons of potential energy, which, being regulated by the speed of the return belt, it delivers to the table in 4 inches of travel. The 30-h.p. quick belt with this assistance is able to accelerate and keep the speed up throughout the stroke, without heating the pulley. Further, the machine will at all times work dead beat between two walls, and plane up to $\frac{1}{8}$-inch landing. The reversal at the end of the quick-return stroke is dealt with quite satisfactorily by the broad belt on the 24-inch driving pully. and this belt motion is struck from the usual form of knocker on the table. The machine will work with certainty at full speed and let the tool drop without marking the work between landings of $\frac{3}{8}$ inch at the start and $\frac{1}{8}$ inch at the finish, fig. 7. The reduction in idle clearance-spaces and the command of good feed-traverses, ranging from 1-32 inch to 1 inch, contribute greatly to the large output of work which has been realized with this machine. By this system of drive with continuous running prime mover, the full power is available at all speeds, and the heaviest chips can be taken at the slowest speed.

The power of the machine, as described, is equal to a 10-ton pull upon the table at the middle speed, and a 15-ton pull at the slow speed. The speeds given are such as could be worked continuously without heating or irregularity down to 12 inches length of stroke. If made without a re-action spring, the return speed, instead of being 136 feet per minute, would be 110 feet per minute, and if driven by shifting belts and without re-action spring, 90 feet per minute.

It will be readily understood that in proportion as machines are made for lighter cuts, they can be returned at quicker speeds, because, as has been said before, the chief inertia lies in the rim of the driving pulley, and this rim must needs be made in proportion to the weight of the cut required. Thus, in a 4-foot-square machine, with a 5-ton pull on the table, fitted with a re-action spring, the quick return of 160 feet per minute can be given, or in a quite simple machine for light cuts, with about 1-ton pull on the table, a return speed of 240 feet per minute is attained without the assistance of any springs. On the other hand, it should be borne in mind that, in a machine for extra heavy cuts requiring a 20-ton pull upon the table, the judicious return speed would be less than that quoted in proportion as the power might be greater.

Reverting finally to the 4-foot-square machine just mentioned as returning at 160 feet per minute, fig. 8 shows photographs of work done on a 6-inch stroke, making 80 reversals per minute, and fig. 9 is the power diagram taken at the same time. In this machine there were two re-action springs, one of which was compressed by the table at the end of the cutting stroke, and the other similarly compressed at the end of the return stroke, so that the table ran in almost complete balance, as shown by the nearly horizontal line on the power diagram. Each hump on that line shows a cycle of the table, 40 of these cycles being completed per minute, involving 80 reversals.

Technical and Industrial Education for the Mechanic*

By Robert Patterson**

The increased and widespread attention being given to the subject of technical and industrial education in our large manufacturing centres makes valuable and timely every expression of views thereon by men whose position affords opportunity to determine the benefits, personal and collective, that accrue from its practice.

BEING interested in the training of apprentices for the mechanical trades and artisans in general, papers read or discussions on the subject, have always been of great interest to me, and when asked to say a few words before the members of your Exchange, I selected this subject, not so much perhaps with a view of imparting new information, as with a view of bringing before you a matter that is of great importance, requiring careful study and attention of the industrial communities of Canada, and those responsible for the proper education of Canadians to-day.

The University Graduate.

The title of my subject to-night might give you the impression that I favored the university graduate, but I might say here that I only partially approve of same, and that a system of combined practical, technical and industrial education should precede any such course.

Papers without number, and discussions without end, have been dealt with to try and settle the question as to whether the university educated man or the practically educated man has been the most successful in giving the best results to his employers and the mechanical and industrial world at large.

Although there have been numerous university graduates who have shown great brilliancy and accomplished much, yet the practical man has not by any means been outclassed, and is holding more positions of high responsibility and trust, to-day, than his university graduate competitor. However it is not this phase of the subject I wish to dwell upon, but the technical and industrial education of the average mechanic or artisan, and the system of education by which it may most successfully be accomplished, both as to thoroughness and economy of time.

Manual Training Desirable.

In this young and growing country of ours, the rapid growth of steam and electric railways, and the vast increase in manufacturing industries, have created a demand for increased and more rapid facilities for doing the work, and for producing mechanics and artisans of all kinds to keep pace with the development. The future will create a still more urgent demand, and to meet present and future requirements a quicker and a more thorough system of education will be necessary to provide properly trained men to meet those requirements.

The men at the head of our public educational system to-day have already realized this, and as a result the boys in our public schools are given manual training. The system should be in force in every centre in the country. It would help parents and guardians by enabling them to judge of the fitness of the boy for his future profession, industrial or otherwise.

It is a great assistance to the boys who intend to enter the industrial profession, and best of all it is teaching them to appreciate, respect, honor and have a desire for honest manual labor, an attitude of mind which will be of incalculable benefit to the individual, and produce a beneficial effect on the country at large.

ROBERT PATTERSON.
Master Mechanic, the G.T.R. Shops, Stratford, Ont.

To begin with, the boy or young man who intends to become a mechanic, or enter any of the industrial pursuits should have a partial high school education, so to ensure a good groundwork for his further development.

During his progress through the shop, and while learning his trade, in addition to his every day instruction, which ought to be under the supervision of a thoroughly trained and competent instructor, his technical training should go on at the same time, and it should be just as much a part of his duties as

*Abstract of address delivered before the Builders' Exchange, London, Ont., on December 7th, 1911.

**Master mechanic, G.T.R. shops, Stratford, Ont.

to turn bolts, fit up a motion, build a stairway, make a writing desk or any other class of work which he is learning to do. In other words, a boy or young man's practical and technical training should be combined, and go hand in hand.

Present School System Requires Amendment.

To accomplish this, I believe our school system should be considerably changed. At the present time the curriculum is furnished by the educational department for our schools, to be strictly adhered to, and as a teacher's qualifications and abilities are judged by the number of pupils which he turns out each year who obtain successful passing marks at the regular examinations, it practically leaves no scope for his individuality, no matter how much he may possess.

A very large percentage of our pupils follow the commercial or industrial lines after leaving school, and yet they are not specially fitted for these, as the whole system of education appears to me to tend toward a general training for university purposes, whereas a very small percentage go to the university.

For instance, it has been my experience and I am sure it has also been the experience of a large number of business men here, that you will find children nine to eleven years of age in our public schools able to read intelligently, write and spell well, and do arithmetic up to long division correctly. When we get these same boys making applications for positions as apprentices in our shops, or in our stores as clerks, we find in a great number of cases, they are not able to spell, write well, or do ordinary arithmetic up to long division correctly. This is when they have arrived at fourteen or fifteen years of age.

Training for Accurate Work.

I think it will also have been your experience that they have not been trained to work accurately. This is the result of crowding of their numerous courses to cover the curriculum. The fair grounding in the rudiments which they get at nine to eleven years of age is not followed up or continued so as to give them a thorough grounding. Our educational authorities have seen fit to abolish the fifth book in our public schools in a great many cases, expecting the pupil to follow into High School for this, but many of those people cannot afford to send their boys to High School, and have to put them to work, and in consequence they do not receive the education, or the groundwork to build one on, which is necessary for them to have to make intelligent mechanics or commercial men.

In most cases, in fact I might say in all our public schools there is an absence of the teaching of practical drawing, geometry or algebra, which subjects were taught in our schools twenty-five or thirty years ago.

Apprentice Training Systems.

While the Manual Training School, if properly conducted and the teaching along practical lines, could remedy a great deal of this, and should, yet up to the present time the instruction is not practical enough, owing to the fact that the teachers in few instances have had practical experience in actual requirements of industries, and I might say the same applies to commercial instructors as well.

In large industrial establishments, and particularly on railroads, the progress has been so rapid during the last few years, that it has become necessary for corporations to start systems for educating young men and apprentices in their own works, as it was found that the supply was becoming totally inadequate to meet the demands.

For instance in the shops over the Grand Trunk System a very thorough system of apprenticeship is in force. A boy desiring to get into our works as an apprentice requires to be between the ages of fifteen and nineteen years. He must be able to read, write and spell intelligently, and do mathematics up to, and including, decimal fractions. If he passes this examination, he is then sent to a medical officer of the company, who examines him physically to see if he is capable of learning the trade, and becoming a mechanic. If he meets these requirements he is then placed in the shops as an indentured apprentice, the indenture binding him for five years. The rates of wages are fixed so as to give him an advance each year.

In addition to this it is compulsory for him to attend instruction classes two nights per week from October 1st until April 1st. Each year examinations are held over the entire system, and apprentices in all the different shops compete. One night a week is devoted to "Mechanical Drawing" and another night a week is set apart for "Practical Mechanics." At the examinations the papers are prepared by outside parties, and when they are turned in they are also examined by outside parties, so that they do not know which shop the papers come from, nor any of the individuals who compete at the examination.

A diploma is then given by the company for the class that takes the highest average marks. In addition to this individual prizes are given at each shop to each class of apprentices and for each year of service. This stimulates the boys, and there is a very keen rivalry over the whole system to have their class obtain the highest average marks, and also for the individual boys to strive to obtain the individual prizes at their own station.

Each year before the apprentice gets his advance in wages he undergoes an examination in drawing and mathematics and the advance is only given on his being able to obtain the percentage of marks required.

In the event of a boy not being able to pass this examination he is given a second trial, and if he then fails, he is dismissed from the service, for the reason that he is either too stupid to learn the business or too indifferent.

As a consequence, after five years practical training in the shops, and five years technical training at these classes, the Grand Trunk always have a corps of well trained young men, who are able to fill any of the positions which become vacant.

The Educated Mechanic a Necessity.

An educated mechanic on railways is very much required to-day, and I am sure you find it so in all branches of industry, but very particularly in railroading, as advances have been so pronounced during the last few years. Heavy power, high steam pressures carried on the boilers, makes it absolutely necessary that we should have the most intelligent men to work on them, and also to construct them.

Tuition for these apprentices is entirely free, teachers, room, light, etc., being supplied by the company, also drawing boards, tee squares and text books, apprentices only being required to find their own drawing instruments and give their attendance. The company also gives two scholarships per year, the successful apprentices receiving four years' free tuition at McGill University.

I believe if this system were extended, and it is a point I wish particularly to emphasize, we would soon have a body of well trained young men able to take positions in every walk of life that was necessary for them to fill, and every well regulated establishment should have young men of this kind coming along. It would keep up the organization of the shop, and we would have more intelligent employes, and get better results.

A Manufacturer's Duty.

I believe that corporations and manufacturers should provide for their employes such tuition, and although it might be somewhat of a burden on the smaller establishments, yet I believe Government assistance could be made available.

Of course this perhaps would not cover all the ground, but it would be a means of spreading a technical and in-

dustrial educational system all over the country, and would be the cheapest and most rapid way in which to get it started.

Government Technical and Industrial Schools.

Then the government should establish thoroughly well equipped technical and industrial schools in the larger centres to give instruction to those who desire it in all the important industries of the country. Any young man who is capable, and wishes a high education, could attend one of these schools, if he so desired, after receiving his practical and industrial training locally. The Government could issue scholarships for competition among those desiring to attend one of these schools.

It would be a great incentive to our boys and young men, and would tend to a general betterment of their education.

A short course of this kind would not take a young man away as long from his practical work as would a four years' course at the university, for in a four years' course he would find so many changes that he would require to go over a great deal of ground again.

One of the difficulties in starting industrial classes of this nature would be that perhaps in the smaller establishments they would not have competent teachers. In the larger establishments there would be very little difficulty, but here is where the government might step in again with available aid, that is, by having a number of trained teachers in each district who could cover a certain area and go from place to place different days or evenings of the week.

Our own Provincial Government has made a commendable start in the matter of industrial classes, and while some have criticised these and say they are practically night classes, yet I consider they have made a splendid start, and where it is found there is a lack of teachers, they should put on a few to cover a certain area as suggested.

Industrial classes, which have just been commenced in Ontario, have been very much needed and the government should give them every encouragement and assistance, as it is the first successful start which will tend to develop them as they should be developed. It should be non-political as far as possible. If left entirely to our educational department things are apt to drift too much into academic teaching, and the desired practical results will not be obtained. My idea would be to hand this particular branch over to a commission of two or three men who would be entirely responsible for its being properly carried out. They would find plenty of work, and if we got the right men who were interested in this subject, it would be a great blessing to our country.

Factors of Success.

In conclusion I would say that the success of these classes not only depends upon the government, but largely upon the individuals of the locality in which they are established. Men who are looking after them should have their work at heart, and be earnest in their endeavors to give the very best education to those seeking it, and if we combine the practical, technical and industrial training of our boys and young men, we should have the best average mechanic and workman, who will meet all requirements of these times of rapid progress and development, and we will, I believe, solve labor problems to a great extent.

My idea in coming here to-night was that after placing these few points before you, we might have a discussion on the matter, which I believe would bring out more points than I have already touched upon, and be beneficial to all of us.

G.T.R. Classes, Stratford.

At Stratford in the Grand Trunk Railway shops we have 117 apprentices who attend classes two nights a week, and on an average we do not have more than two absent, and that is only when they obtain leave of absence, or through sickness. In regard to our industrial classes which are held on the same night, we have an average attendance of about 170 students. At the latter classes we found that we could not accommodate all who desired to attend, not having sufficient teaching staff, but we are in hopes during next year, with the start we have been able to make, that we will be able to accommodate all who may desire to come.

C. P. R. BRIDGE, LACHINE, P. Q.

The Foundation Company which has been at work since the month of July, 1910, enlarging the piers of the Canadian Pacific Railway bridge over the St. Lawrence river from Highlands to Caughnawaga, has completed that important undertaking, and the superstructure which is being put up by the Dominion Bridge Company, Montreal, will also be completed early in the coming year.

INDUSTRIAL ACCIDENTS.

Ninety-five fatal and one hundred and ninety-one serious injuries to workpeople were reported to the Department of Labor during November. The record is considerably more favorable than that of the preceding month or that of the same month last year. In October there were 344 accidents, fatal and non-fatal, and in November, 1910, there were 407. The chief accident during the month was the foundering of the schooner Antigua, off St. Martin's River in the Gulf of St. Lawrence, when the captain and eleven sailors were drowned. There were eleven killed in the railway service, eleven in the agricultural pursuits and twelve among unskilled laborers. The largest number of non-fatal accidents occurred in the metal trades, namely, forty-five, but the twenty-three non-fatal accidents reported in the railway service were of a more serious character.

C.P.R. APPRENTICE SCHOLARSHIPS

The annual presentation of scholarships to the C.P.R. railway apprentices at the Winnipeg shops took place on December 22 last. These scholarships, five in number, are awarded annually upon the result of the examination based on the year's work. As is, perhaps, generally known, the C. P. R. has instituted an apprentices' instruction department, which is at present under the charge of E. E. Bailey as supervisor. In the unavoidable absence of W. E. Woodhouse, superintendent, Mr. Nield, the general locomotive foreman, presided at the meeting in the instruction room, where nearly 100 apprentices were gathered.

After some congratulatory remarks upon the work of the apprentices and that of Mr. Bailey, the supervisor, the chairman announced the result of the examination, the first eight on the list being as follows:—L. Woodhouse, P. Prior, A. Cuthbert, N. Williamson, J. Kenyon, J. McGregor, J. Brophy, H. Edwards.

L. Woodhouse, being occupied with other studies, stood out, while Cuthbert and Williamson, having previously won similar scholarships, were not again eligible. Prior, Kenyon, McGregor, Brophy and Edwards, therefore, become this year's winners.

Before the close of the proceedings, E. E. Bailey was the recipient of a presentation in the shape of a $20 gold piece in a suitable case, the gift of his pupils, together with a brief, but appreciative testimonial of their gratitude for his care on their behalf. After Mr. Bailey had suitably responded, the meeting broke up.

L. Woodhouse (son of the superintendent of the shops), Prior and Edwards, being all junior boys, makes their performance all the more creditable.

The Plant of The Canada Forge Co., Ltd., Welland, Ont.

By J. H. Williams*

A plant for the production and supply of heavy forgings is a prime necessity in every large engineering and industrial district, and the foresight which determined the establishment of the Canada Forge Co., has been amply justified. Growth of business, and extension developments in buildings and equipment to meet it, have been the reward and work of the management, and although, even now, the claim of being considered among the Dominion's leading industries is justifiable, we look for, within the next few years, a further strengthening of its cords and stretching of its stakes.

THE CANADA FORGE CO., LTD., have been established at Welland, Ont., for the past five years, during which time they have built up a reputation for high quality forgings in steel and iron. The plant, consisting of forge and blacksmiths' departments, together with a well equipped machine shop, is situated on five acres of land adjacent to the Grand Trunk Railway tracks. Raw material, in the form of ingots, billets, flats, squares, etc., is received in the yard at the south end of the plant and unloaded from the cars by a derrick, for storage until required. A truck, running on an industrial railway, which forms part of an extensive system, conveys the stock from the yard to the forge shop.

Forge and Blacksmiths' Shops.

The forge and blacksmith departments are in one building, which covers an area of 140 by 50 feet. For blacksmith work, there are 5 smith's fires, and a 2,000-lb. single frame steam hammer served by 2 jib cranes. The stock is heated in a 72 x 48-inch coal-fired furnace, the latter being equipped with a steam-driven automatic stoker. The products of this department consist of general heavy blacksmith work, dredge and steam shovel dipper teeth, rings of all sizes, etc. In the forge, heavy pieces such as crank shafts, connecting rods, crank pins, gear blanks, axles, etc., are turned out, special attention being given to marine and locomotive requirements.

In order to better cope with large work, a 500-ton hydraulic forging press is now being installed. This massive tool works under a water pressure of 3,000 pounds per square inch. The pump for operating is of the horizontal single acting three-throw type, with plungers 1 9-16 inches diameter by 15¾ inches stroke. It is driven through direct gearing by an 85 h.p. A. C. motor. The accumulator ram is 9 13-16 inches diameter, and the stroke 12 feet. This press will be served by two jib cranes and two coal-heated furnaces fitted with automatic stokers. Forgings will be produced up to 30 inches diameter and 30,000 pounds weight. A third furnace serves a 2,500-pound double frame hammer. Waste heat from the furnaces raises steam for the hammers in two return tubular boilers, the feed water for which is taken care of by two 5¼, 3½, 5-inch horizontal duplex pumps, and feed water heaters.

Blast for the furnaces is supplied by two blowers; one being belt-driven and operated by a 10 h.p. A. C. motor, and the other direct connected to a 25 h.p. A. C. motor. The forge is equipped with an annealing pit 15 feet long by 6 feet wide, wherein all high-carbon forgings are annealed and heat treated.

Machine Shop.

The machine shop is separate from the forge, material from the latter being conveyed by a 5-ton electric crane running on an overhead mono-rail track connecting the two departments. Although in a plant of this description, machining consists for the most part of rough turning, slotting and planing, there is here notwithstanding, every facility for the performance of finely finished work when called for. This shop is in three bays, and covers an area of 100 by 60 feet. The machine tools are all of the most modern description, and include the following: Two

Canada Forge Co. Machine shop, looking south.

heavy duty lathes, equipped with direct-geared motor drive to patent heads, swinging 27 and 30 inches, and taking 8 and 18 feet between centres respectively. The 30-inch lathe is used chiefly for turning large crank shafts: A 36-inch cone-driven lathe taking 8 feet between centres; a 36 by 36-inch by 15 feet planer; a 42-inch heavy forge lathe, triple geared, with 16-foot bed; a 16-lathe with 35 feet centres; an 18-inch tool room lathe, on which bolts and nuts are made and general repairs are handled; a cylindrical grinder 20 by 96 inches, used for finish-grinding crank shafts, street railway axles, etc., and driven by a 20 h.p. A. C. motor, embrace and give the reader an idea of prominent features of the works machine tool equipment.

small electric drill. The latter is mounted on the top of a large square threaded screw passing through the bed of the machine, so that the height of the drill can be adjusted to suit various diameters of shafts. After being rough-turned, the forgings are cut off to length on a 31-inch belt-driven cold saw. For cutting out crank throws, a motor-driven cold saw with two 30-inch blades

Canada Forge Co. General View of Plant.

inch slotter with special tool holder, which enables two outside cheeks of a crank to be slotted at one operation, the tool holder consisting of a steel block with checkered face, against which, the slotter tools of square section, are clamped with studs and straps. A 36-inch drill press; a 36-inch shafting

Mention must be made of an ingenious centering machine designed by the company, and to which all forgings for turning are first taken. The shaft to be centered is supported on anti-friction disks in the usual way, and the centering is done by a combined drill and countersink mounted in the spindle of a

is installed. Both saws have inserted teeth of high-speed steel.

The officials of the Company are:—Thomas J. Dillon, president; John L. Emerson, vice-president; Frank C. Hesch, secretary-treasurer, and at present, a force of 40 ment are kept fully employed.

DEVELOPMENTS IN MACHINERY

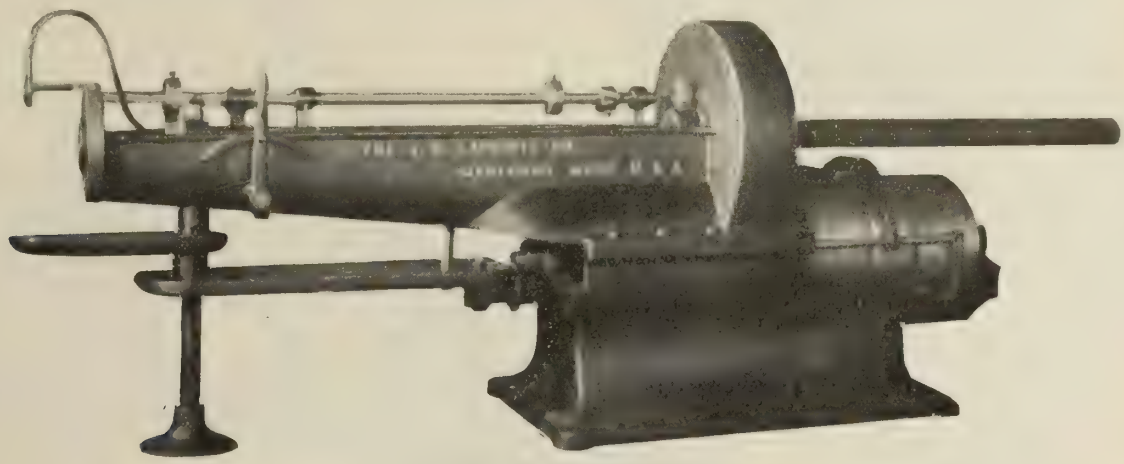
A Record of New and Improved Machinery Tending Towards Higher Quality and Economical Production in the Machine Shop, Blacksmith Shop or Planing Mill.

BROACHING MACHINE.

THE description and illustration refers to an improved Broaching Machine manufactured by the J. N. Lapointe Co., Marlboro, Mass. The frame consists of two parts, the bed being mounted on a base, and the capacity of the mechanism embraces from the smallest to the heaviest broaching practicable. The pulling apparatus includes a sliding head, pulled by a 2¾ inch screw passing through the hubs of the main gear, in which a special composition nut is inserted, for instantaneous removal as replacement requires.

In order to overcome the friction to which these machines have been subject when the load is applied, a large ball bearing thrust is fitted. A two-speed arrangement is provided, the change of speed being obtained by a sliding gear connected direct to the driving gears. This particular feature will be found advantageous in accommodating various classes of work. The machine has a positive geared drive and return; its driving mechanism being of the simplest possible type, and similar to that of a planer having one tight and two loose pulleys. A large tube attached to the rear end of the machine forms a protection to the screw against dust accumulated by the belts. Under the front end are two lugs to which a special supporting table may be fastened by means of screws.

The driving wheels run in a greased chamber, the necessity for oiling them being thereby eliminated. Due to the fact that neither pins nor a positive clutch enter into the driving of this machine, it being simply a question of belts shifting on tight and loose pulleys, any desired speed is obtainable without risk of injury. The pulley power has been demonstrated by a series of severe tests, and as an example it may be mentioned that 1½ inch holes have been most successfully broached on steel castings, 15 inches long. An automatic oil pump, for flooding the work with oil while being broached, and a countershaft complete, form part of the inclusive outfit.



Improved Broaching Machine.

SINGLE MOTOR SELF-PROPELLING CRANE.

THE accompanying illustrations show a self-propelling single motor railroad crane, which is, at once, simple, economical and efficient for the lighter operations required of this class of machinery. Because of these advantages, it is rapidly finding a place in the equipment of factories and yards which

Fig. 1—The Browning Engineering Co. No. 4 Four-wheel Locomotive Crane.

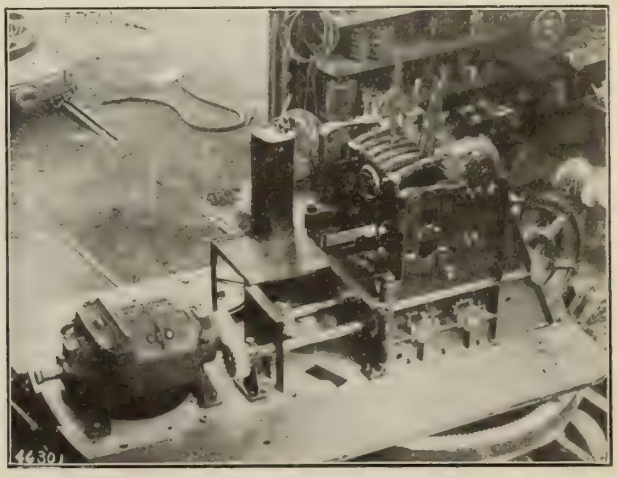


Fig. 2—Motor Connections, etc., No. 4 Four-wheel Locomotive Crane.

have only a limited use for cranes and hoisting apparatus generally.

The machine shown in Fig. 1 is known as the Browning Engineering Company's standard No. 4, four wheel locomotive crane. It is operated as a crane and propelled by a motor, under the control of one man. It has a maximum lifting capacity of 15 tons at ten feet radius and 2½ tons at forty feet radius. The working weight is approximately thirty-five tons. The draw bar pull of about 7,600 pounds enables it to handle six or seven cars on a level track. The motor, known as Type MT. No. 2, is built specially for crane service. It has a heavy frame split horizontally so that all the parts are easily accessible. The shafts are extra large and strong, and the area of the commutating surface ample for good commutation. The current density in the brushes is low. High starting torque and low fly wheel effect permit of quick starting, stopping and reversing as required by the particular service. The motor shown is rated at 50 horsepower, 220 volts and 470 revolutions per minute.

Fig. 2 gives a detail view of the motor connections and the mechanism in general. Standard reversing drum type Westinghouse controller and grid resisters are used for controlling the motor.

REMOVABLE SPLIT RIM SPROCKET.

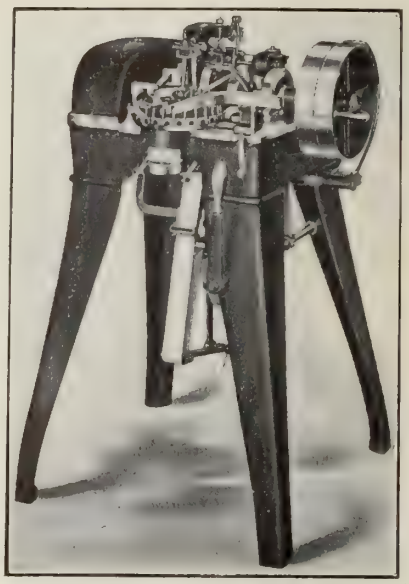
THE accompanying cuts show the Yankee Patent Removable Split Rim Sprocket, a recent development. The body is shown solid with set screw attachment, but is also made split when required. The drive on the rim is borne by the solid lugs, the bolt being used merely to keep the various parts in position.

The Yankee is intended for heavy service, where wear, due to dust and grit conditions, is excessive, such as in cement mills, ore, coal or ash elevators. A prominent feature of the new device is its economy, for, when the rim wears down, it can be replaced at about one-third the cost of a new wheel. Again, it is not necessary to remove the sprocket from the shaft, the change of rim being accomplished in place.

The A. M. Ellicott Co., 301 St. James St., Montreal, sole owners of the Canadian patents, carry a full line of sprockets together with spare rims to suit all ordinary sizes of link and roller chains.

A CARAMEL WRAPPING MACHINE.

THE Holden-Morgan Co., 50 Pearl St., Toronto, manufacturers of special machinery of all kinds, have recently completed five ingenious machines for wrapping caramels, one of which is herewith illustrated. Fellows & Hopkins, Middletown, N.Y., who build them in the United States, supplied the designs.



Caramel Wrapper. The Holden-Morgan Co.,

The operation of the machine is as follows:—The material for the caramels is first rolled to the correct thickness in bars or slabs 5 ft. to 6 ft. long. These go next to a scoring machine, and are cut into strips of the proper width to fit the chute seen at the front, near the pulley. Two girls, one to feed and one to pack the wrapped caramels, are in attendance. The machine stands between two tables, the total floor space occupied, inclusive of tables, being about 4 feet by 12 feet. The candy is brought from the scoring machine to the table on the right of the wrapper and is fed into the chute already mentioned. When starting up, it is of course necessary to push the candy into the whole length of the chute so that it be engaged by the projecting pieces on the rotary table. It is then drawn in automatically. This rotary table, or rotary cutting plate, as it is more correctly called, is fitted with twenty-four knives operated by an eccentric pressure plate below. The candy is delivered to the cutting plate at the front and travels round to the back, by which time it is completely cut through. In the meantime, the wrapping paper has been cut off from the continuous roll below the machine and together with the caramel is pushed into the grooved rim of the wrapping wheel at the back of the machine. Three more movements complete the wrapping, after which the caramel passes down a second chute to the packing table. The whole operation takes but a fraction of a second, the machine being guaranteed to satisfactorily wrap 240 caramels per minute. The power required is about 1-10 horse power

Yankee Patent Removable Split Rim Sprocket, Assembled.

Yankee Patent Removable Split Rim Sprocket, Knock-down.

There is a large amount of fine delicate work in a machine of this kind, and it speaks well for the equipment and reputation of the Holden-Morgan Co., that they should have been entrusted with the order.

DISC GRINDING IN THE PATTERN SHOP.

THE disc grinder is coming to be recognized as a valuable adjunct to the up-to-date pattern shop, not only because it is a great time saver, but also on account of the high degree of accuracy obtainable by its use.

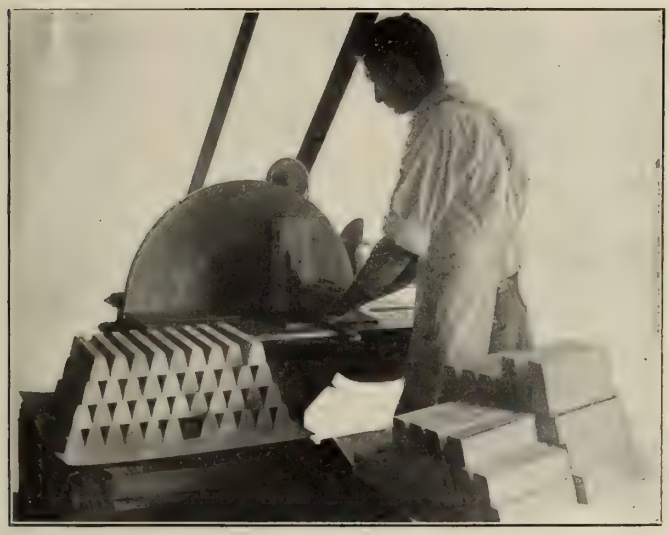


Fig. 2.—Gardner Pattern-makers' Disc Grinder

In keeping with their reputation as prominent manufacturers of disc grinders for all purposes, the Gardner Machine Co., Beloit, Wisconsin, a short time ago, added to their line a grinder especially adapted to pattern-making. This machine is made in several styles and sizes, fig. 1 showing the No. 18 grinder. This has two 30-inch discs, which run at 756 r.p.m., and are driven by a 5-inch belt. One of the principal features is the univerasl work-table, the weight of which is supported by a counter-balance within the base of the machine through the medium of a cable passing over a grooved pulley at the top. The table may be tilted to any angle with the face of the wheel, a graduated segment enabling the angle to be accurately determined. The tilting axis is so designed that the inside edge of the work-table always remains close to the face of the wheel, regardless of its angular or lateral position. Attached to the left-hand table, fig. 1, may be seen a universal angle gauge. This gauge or protractor head is a great convenience for squaring pieces, and in producing angles and draught. It is graduated from zero to forty-five degrees in either direction. By the use of these graduations in conjunction with those on the head of the table, any combination of angles may be quickly and accurately obtained.

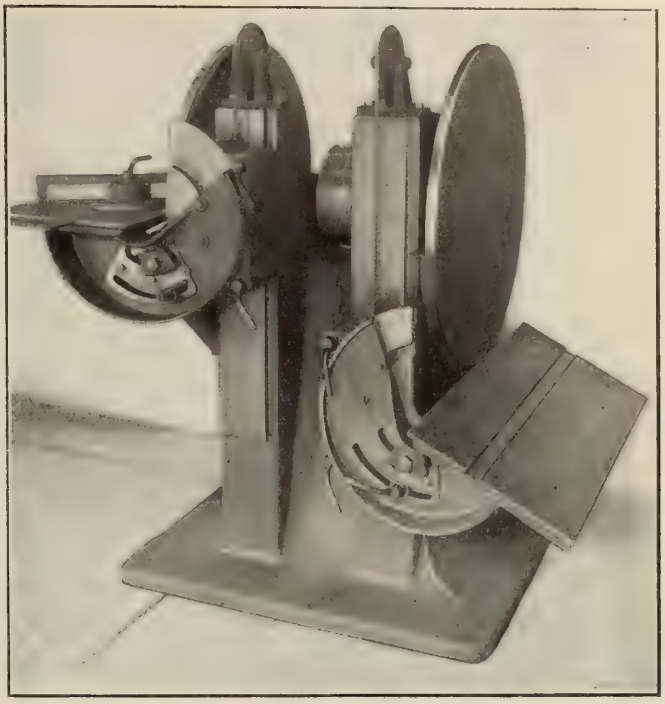

Fig. 1.—Gardner Pattern-makers' Disc Grinder

The guide bar of this attachment is adjustable, so that when the table is tilted or the gauge set to an angle, the bar may be moved to right or left, thus

Fig. 3.—Gardner Pattern-makers' Disc Grinder

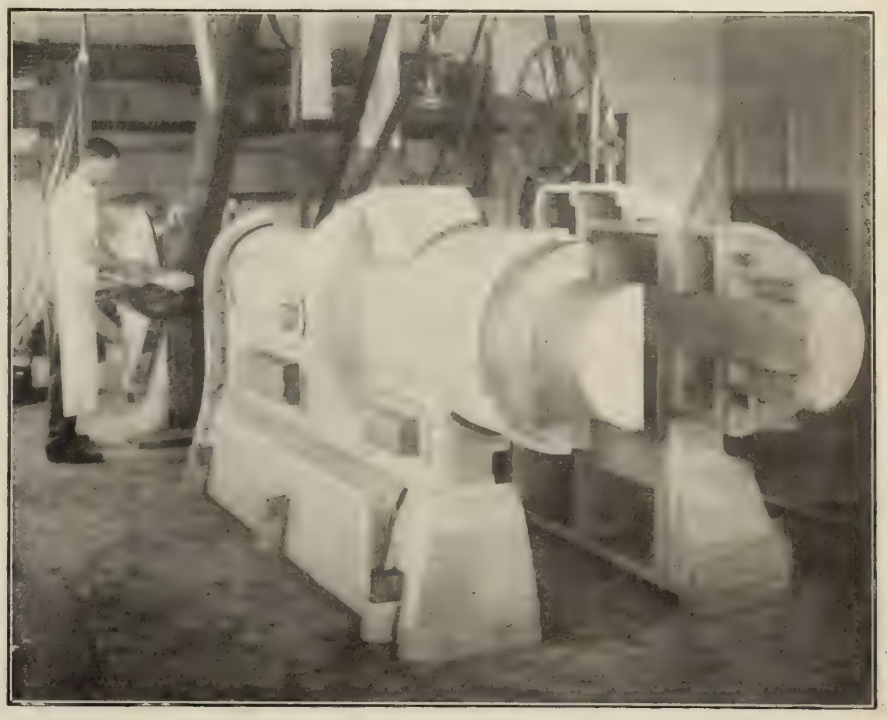

Fig. 4—Gardner Pattern-makers' Disc Grinder

keeping one end always close to the wheel. When adjusted, a hand nut locks it in the required position and at the proper angle. Another attachment supplied with the machine is the circular core-print gauge for producing round or curved surfaces. The work is pivoted on a pin driven in at the proper radius, and swung against the wheel. An adjustable stop screw regulates the amount of stock removed and also makes it practicable to produce duplicate work. Tilting the table, of course, puts a taper on the work.

Fig. 2 shows a practical adaptation of this attachment to the making of teeth for a gear pattern. The operator is seen producing the curve of the teeth. The blocks, 8 inches long by 2½ inches wide by 3 inches high, were first made parallel on the universal duplicating gauge—another attachment supplied with the grinder,—and then squared up on the ends by using the universal angle gauge. A simple wooden fixture was used for holding the blocks, and by means of the circular coreprint gauge, the fixture and block were swung against the wheel. The table was tilted one-half degree to produce the required draught. The stop screw enabled all the 96 teeth to be made exact duplicates, and it is estimated that the work was done in one-tenth of the time it would have taken by the old method. In addition, it was done more accurately and with better finish.

Fig. 3 shows the completed gear pattern. Most of the machine work on this was done on the pattern-maker's disc grinder; all the segments used in the outside rim being ground parallel to size and glued-up on the face plate before being put in. All pieces in the spokes were made parallel and squared up on the grinder before the glueing operation, and the round hubs, plates and coreprints ground with taper by use of the circular coreprint gauge. From the foregoing it will be seen that hand or machine planing or trimmer work on the pattern was entirely eliminated.

Fig. 4 shows the pattern for the front, or cylinder half, of a 150 h.p. gas engine, a large portion of the work on which was done on a disc grinder. Thus, the staves forming the cylinder barrel and coreprints were all gotten up on the grinder, resulting in perfect glue joints throughout, without the use of a plane or other tool or machine.

Knots, cross grains, end grains, hard or soft woods, and even projecting nails or screws can be worked without difficulty, and the grinder may also be used on metal pattern work. When renewing the abrasive discs, it is not necessary to first remove the wheels from the spindle, since the Gardner Machine Co. supply a special cement for attachment, thus doing away with the necessity for a wheel press.

THE GOSPEL OF EFFICIENCY.

IF we miss the right way to universal happiness and prosperity in the twentieth century, it will not be for the want of teachers and preachers. From the moment of our birth (or even earlier) the best method of handling us is described at great length in print, and if we had time to read thereafter all that is written concerning Education, Success in Business, Personal Hygiene and Applied Psychology, we should no doubt escape all the ills that flesh is heir to and only decide to die when thoroughly bored with things always going right and never wrong.

This same efficiency or allrightness is universally desired by those responsible for armies and navies, factories and mines, and publicly and privately organized effort of any kind. Nothing is easier than to look round and see that some one is apparently shirking instead of working, or that two men are pulling against each other, back to back, instead of shoulder to shoulder, or that there are millions wrongly fed or badly housed or imperfectly trained. In fact, any fanatic prophet of efficiency must find it difficult to avoid the temptation to throw up his hands in despair and incontinently drown himself.

A World of Waste.

Wherever his penetrating incandescent glance may fall, behold, it is all wasteful. The walrus and the carpenter wept to see such quantities of sand—unused. Nothing is easier than to observe such phenomena of natural and human extravagance and neglect, and to make sententious remarks about it. Yet nothing is harder than to deliver spoken or written advice that is not bald, flat, commonplace and unconvincing. Under sublimely enlightened general management with a free hand it is possible that the world's work could be done far better and with much less trouble, but it is only the dreamers—themselves atrociously inefficient—who cherish such thoughts. The hard-headed practical man who gets things done is only attracted by the gospel of efficiency in so far as it may enable him to get the better of his competitors in money making. He would dismiss any more general appeal with the very plausible theory that you cannot get much efficiency except under the spur of self-interest.

Failure's Eplanation.

It is most curious that the people who preach to us are not usually those who are accomplished practicians. Great generals and admirals do not write text-books on tactics, neither do millionaires tell us how to make fortunes. They pretend to do so sometimes in newspaper interviews, but the really interesting advice comes from those who have been through the bankruptcy court. Nothing indeed is so helplul to the young and ambitious as the candid record of failure, intelligently explained. In business especially, the most useful thing to know is what not to do. General advice of this negative character may be really serviceable; but for the positive purpose there is nothing available except the native sense and wisdom of the hero himself. Many men established in a comfortable way of business advance steadily by mere industry and scrupulous attention to a set of rules that could be written on a half sheet of note paper, while there are many failures who have fallen just because their much superior intellect has not been yoked to the proverbial prudence of the ages.

Over-drilling.

There are foods of high nutritive value according to analysis, which require such an expenditure of energy in their digestion that the more the consumer eats the sooner is he likely to die of starvation. Similarly, the conscientious disciple of efficiency may pay so much attention to the admired rules and machinery prescribed that he may find himself short of time and energy for doing the real work of the day. There are men who become the slaves of their filing systems, or who worry themselves into ill-health over trivial faults in office routine. Periodic relaxation is quite as important as concentrated application.

While, on the whole, it may be true that most men are not reaching their maximum output of work, and that, if they were driven at their full load capacity, the results would be astonishing for a time, it is perhaps a healthier state of things that there should be this margin of potential effort left unemployed except on occasions of emergency. Over the top of efficiency is the precipice of breakdown—Electrics.

In speaking of increasing efficiencies in workshops, a prominent shop manager says that manufacturers are just beginning to resolve into first principles the various manufacturing processes of their finished products. They have yet to apply this analysis in exactness to the problem of machine efficiency in the manufacture of their products. He stated that he believed that there is a lack of knowledge of the possibilities of the most common type of machine tools in every shop; in fact there is not one shop in 10, in which the possibilities of even the engine lathe are thoroughly understood.—Ex.

Horse Power Years vs. Kilowatt Hours: Which Pays Best?

By H. E. M. Kensit, M. Inst. E.E.

The management of industrial enterprises, using electrical power in the manufacture of their product, will find the information contained in this article particularly valuable, showing as it does, by easily followed reasoning and calculations of a simple nature, the procedure to be adopted in discriminating between the two well-known forms of electrical power contract, so as to secure an outlay commensurate with the exacted service.

MANY manufacturers and other power users, when making contracts for electric power, are given the option of taking it at a price per h.p. year or a price per k.w. hour. Few such persons are in a position to decide which system of rating will be cheapest, and the object of this article is to enable power users, unfamiliar with the special technical points involved, to clearly decide which plan will secure them the lowest annual cost. Taking any given schedule of prices charged by an electric power company, there are very few cases indeed in which the supply to a factory would work out to the same annual amount, when charged on the h.p. year or k.w. hour basis, and in many instances the difference in favor of one or the other would be very marked.

There are three phases of the question to consider :—

1. Where a calculation, based on conditions of work that can be foretold with a fair degree of accuracy, shows so large a margin in favor of one or other of the methods, that no probable variation in these conditions would change the result to any considerable extent.

2. Where a similar calculation shows no decided margin in favor of either system of charge.

3. Where a factory has been previously electrically operated, and records of maximum h.p. used and k.w. hours consumed have been kept for a sufficient time and with sufficient accuracy, to show closely the actual conditions of work.

Load Factor.

The three cases will be separately discussed in detail, and as the whole solution centres mainly on "load factor," it is necessary to have a clear and exact idea what is understood by this, and how it affects the subject under consideration.

The term load factor means the ratio between the power, or more correctly, the "energy" actually used and what would have been used during the same period, if the maximum or peak load had been maintained for the whole of that period. It is, therefore, affected both by hours worked and by the relation between the maximum and average power used. In order to get reliable results, the load factor should be taken over a whole year, in order to eliminate varying results at different seasons. It should also take 365 days per year into account, and not working days only, for power, taken on the h.p. year basis, is paid for and may be used every day of the year.

Very brief consideration will show, when power is taken per h.p. year, that the more nearly what is actually used approaches the greatest amount possible to have been taken during the like period without increasing the peak load, the the cheaper does the power become in relation to useful work done, in other words, the load factor is high, and under these conditions, the h.p. year method of charge is the most favorable to the user. It is obvious that if $20 per h.p. year is paid for unlimited hours of use, it is a better bargain if the power is used for 24 hours a day, and 7 days a week, than if it is used for only 9 hours on 6 days a week. Conversely, in the case of a low load factor, where power is used only intermittently, the charge per k.w. hour is likely to be most favorable to the purchaser.

Example of Load Factor.

To give a concrete instance of working out the load factor, suppose a factory, with motors totaling 100 h.p. installed, whose peak load over any appreciable period does not exceed this, but averages 75 h.p.; also that the daily hours of work are nine, and the working days 300 per annum. The total working hours would then be 2,700, out of a year's total of 8760. The load factor, due to average load being less than maximum, would be $100 \times \frac{75}{100} = 75\%$.

The load factor, due to actual hours being less than total possible, would be $8760 \times \frac{100}{2700} = 31\%$, and the actual load factor would equal 31 p.c. of 75 p.c.= 23p.c.

For convenience we may use the formula:—Per cent load factor=

$$\frac{\text{H.P. hours actually used} \times 100}{\text{Peak load} \times \text{total hours per year}}$$

In the present example this will be :—

$$\frac{75 \text{ H.P.} \times 2700 \text{ hours} \times 100}{100 \text{ H.P.} \times 8760 \text{ hours}} = 23\%$$

load factor.

The actual load factors obtained under working conditions with electric drives are always much less than would be anticipated from a consideration of maximum power used and hours worked. This is due to various inherent economies in the electric drive which are now fairly well understood, but which are outside the scope of this article. Electric driving lends itself to accurate measurement of the actual energy or K.W.H. used, and the maximum peak load occurring in a given period.

Load Factors from Typical Factories.

The following list of load factors obtaining in a few typical classes of factories may be of interest. The figures as to per cent of average load to connected motor load (total rated H.P. of motors installed) are taken from a paper read by Mr. E. W. Lloyd before the National Electric Light Association, and check closely with many similar results from other sources. The annual load factor is deduced from this on the basis of a 54 hour week.

TABLE I.

Kind of Work.	% of average load to connected motor load.	Annual load factor if operated 54 hrs. per week = 31% of full time.
Boiler shops	27%	8.4%
Sheet metal	27	8.4
Soap making	28	8.7
Wood working	33	10.2
Machine shops	35	10.9
Furniture	36	11.2
Boots and shoes	43	13.3
Clothing	45	14.0
Box making	45	14.0
Cotton mills	60	18.6
Woolen mills	71	22.0
Average	41%	12.8%

It will be seen that the average load is only about 40% of the rated H.P. of the motors and the average annual load factor on a 54 hour week is only from 12 to 13%. Now, it is quite usual when power is sold on a H.P. year basis to fix the charge on the total rated H.P. of motors connected, and in such a case, it will be seen that the manufacturer is

often only using 12 to 13% of the power he is paying for, and entitled to use.

In other cases, instruments are installed to measure the actual peak load taken, and the charge is made on the highest reading, lasting at any one time from 5 to 30 minutes, according to the schedule of the power company. This is a much more equitable arrangement, and a specified period of even 5 minutes will be sufficient to prevent the momentary excess load, due to starting a machine, from raising the bill above that due for ordinary maximum load.

In such operations as cement-making, refrigeration, pumping, etc., in which there is a steady 24 hour load for most of the year, the annual load factor may be as high as 80 or 90%.

Comparison of Methods of Cost Charge.—I.

We may now proceed to a comparison of the two methods of charge in some specific cases. Reckoning the alternative charges offered to be $25 per H.P. year, based on the rated H.P. of motors installed, or 2½ cents per K.W. hour, and taking first, the boiler shop (table I.) with a load factor of only 8.4%, and assuming it uses 30 H.P., then, on the H.P. year basis the charge would be:

30 H.P. at $25=$750.

For the K.W.H. basis, we must remember that the motor is rated on its output, and the charge for electricity per K.W.H. is made on the input; in other words, the power user pays for the loss in the motor. An average efficiency for motors, from 5 to 50 H.P., may be taken at 85%. One horse power = 746 watts, and 1 kilowatt = 1000 watts, so that $\text{H.P.} \times \frac{746}{1000} = \text{K.W.}$

30 H.P. output at 85% efficiency = 35.3 H.P. input, and

$$35.3 \text{ H.P.} \times \frac{746}{1000} = 26.4 \text{ K.W.}$$

The load factor of 8.4% is due to both intermittent use and varying load, but it introduces no error to assume, for the purpose of this calculation, that the plant worked at full load for very short hours. We, therefore, take the whole percentage off the hours.

$$8760 \text{ hours per year} \times \frac{8.4}{100} = 735 \text{ hours.}$$

735 hours × 26.4 K.W. = 19,400 K.W. hours.

19,400 K.W.H. at 2.5 cents = $485.

The annual saving in favor of the K.W.H. basis is therefore $265 or 35% and it would probably be safe to make the contract on that basis.

Comparison of Methods of Cost Charge.—II.

Next take the case of the furniture factory with a load factor of 11.2%. Working this out in exactly the same way, we have:—

Annual charge on H.P. year basis=$750

Annual charge on K.W. H. basis=$650.

In this instance it will be seen that the margin is small, and a slight change in the estimated working conditions might throw the balance either way. The manufacturer, where he has the choice of two rates, should, under such circumstances, stipulate, before making a contract for a term of years, that he shall have the option of changing to the other rate after one year's trial. He can then instal his own electrical measuring instruments, and after a year's run will be in a position to decide which rate will give him the cheapest power.

Comparison of Methods of Cost Charges.—III.

Again, take the case of the woolen mill with a 22% load factor. Worked out exactly as before, this shows:—

Annual charge on H.P. year basis=$750

Annual charge on K.W.H. basis=$1275.

Here, the margin in favor of the H.P. year basis is so large that no probable change in working conditions could turn it the other way, and, therefore, no further consideration is necessary.

To simplify the examples, only 30 H.P. has been used throughout, therefore, the totals given are small, but in the case of factories using hundreds of H.P., the annual sum involved may be large, and the question is then worthy of the most careful consideration before making a contract.

Comparison of Methods of Cost Charge.—IV.

Lastly, take the case of a factory which has operated its own electric power plant. If records have been kept of the peak load and K.W. hours used, and of the cost of producing same, then the cost per K.W.H. is known. If it be under consideration to take supply from an outside source on a H.P. year basis, then the price, equivalent to the present cost of producing, would be:—

$$\text{Price per H.P. year} = \frac{\text{K.W.H per annum} \times \text{cents per K.W.H.}}{\text{Peak load in H.P.} \times 100.}$$

To illustrate the foregoing points we have discussed, Table 2, follows: Assuming $25.00 as the price paid per H.P. year, based on rated output of motors installed, and that the average efficiency of the motors is 85%, then this table shows the price per K.W.H. that would be the equivalent of $25 per H.P. year at different load factors.

TABLE 2.

Price Per H.P. Year	Load Factor	Equivalent Price Per K.W.H. in cents.
$25	8%	4.06
25	10	3.24
25	20	1.08
25	30	1.62
25	50	0.65
25	70	0.46
25	90	0.36

INSPECTION OF LOCOMOTIVES.

After January 1, 1912, the inspection and testing of locomotives on all the railroads under the jurisdiction of the Railway Commission of Canada will be governed by new and rigid rules which the Board has issued to every road affected.

They provide that companies are to be responsible for the general design and construction of locomotive boilers under their control; that a safe working pressure is to be fixed by the chief mechanical officer of the company or a competent mechanical engineer under his supervision; that the mechanical officer in charge, at each point where boiler work is done will be held responsible for the inspection and repair of all locomotive boilers.

It is ordered that not less than once each month, or fifteen days after inspection, a report of such inspection is to be filed with the chief operating officer of the board for each locomotive used.

In case of accident from failure of locomotive boilers or their appurtenances, resulting in serious injury or death, the company owning or operating the locomotive is required immediately to wire the board's operating officer regarding the accident and the complete list of killed and injured.

A penalty of $100 is fixed for contravention of any of the clauses in the new order.

STEFFENS & NOLLE OPEN CANADIAN BRANCH.

Among the firms who have recently entered the Canadian markets is the large German house of Steffens & Nolle, Ltd. The head office and factory are in Berlin, Germany, where they have over a thousand employes. The firm is capitalized at $2,250,000, and their Canadian headquarters is Room 27, Beardmore Building, Montreal. They are carrying a full line of hardware, wood and metal-working machine tools, and will also handle heavy iron goods, including structural steel, sheet metal, seamless drawn tube, steel sheeting, forgings and castings. Mr. W. Steffens is manager of the Canadian branch, and Mr. R. W. Bartram, for some years purchasing agent for the Allis, Chalmers, Bullock Co., is prominently connected with the firm.

CANADIAN MACHINERY AND MANUFACTURING NEWS

A monthly newspaper devoted to machinery and manufacturing interests, mechanical and electrical trades, the foundry, technical progress, construction and improvement, and to all users of power developed from steam, gas, electricity, compressed air and water in Canada.

Vol. VIII. JANUARY, 1912 No. 1

THE OUTLOOK OF 1912.

IN ITS broadest sense, the advent of this Year of Grace, 1912, may be said to presage an auspicious outlook. Notwithstanding the disturbing and distracting effects of political changes in home government and the more or less uncertainty apparent in the realm of Imperial relationships, it falls to be recorded that Canada, during the year just gone, has kept steadfastly on the even tenor of her way towards an increased and highly satisfactory development in almost every sphere to which men, mind and matter are contributory agents. The natural inclination, however, is not to dwell on past achievement, and it is well, perhaps, that it be this wise. New and important considerations, hitherto undreamt of projects and developments, discoveries of almost miraculous import and pressing social problems will, in the future each bear a part in the molding of our personal and national upbuilding, and we may not shut our eyes and stop our ears when they present themselves and voice their demands.

The industrial outlook, which in large measure is that of machinery and the mechanical arts, was never, we are safe in saying, so bright in the history of this Dominion, as we find it to-day. Men of all shades of political, administrative, civil and social opinion, in every rank and station, have expressed themselves as satisfied to the point of being optimistic, regarding Canada's agricultural and industrial near-future possibilities. The wealth uncovered has but revealed resources, by comparison, to stamp the former as a mere scratching of the ground, and who shall gainsay the prediction that for this New Year and those to follow, the mine, the blast furnace, the smelter, the foundry, the boiler shop, the forge, the rolling mill and the machine shop, will each be taxed to an increasing extent to keep pace with our individual needs and discoveries.

Questions of more than ordinary importance have already arisen from this healthfully abnormal condition, and it may here be observed that pressure, for wise decision and action upon them, is urgently felt. Prominent among these may be cited the Georgian Bay Canal, the Welland Canal, the Canadian Navy, workmen's compensation, the problems of labor, technical education, the interference of politics, mergers, trusts, etc. Beyond the sphere of the foregoing, and touching what might be termed external affairs, every citizen of this Dominion, in his capacity of being a responsible unit of a great Empire, must intelligently follow and study such momentous issues as Imperial relationships, the root cause and general effects of the recent great railway strike in England, and the certain changes which the opening up of the Panama Canal will produce on a large portion of Canadian imports and exports. Our country is off to a good start and sane, "douce" and determined men are, in a majority, exerting a firm control. As a result, not only is well regulated progress and development for the welfare of our own citizens being secured, but the confidence of sister nations from a trade and investment point of view is also being clearly manifested.

In manufacturing circles, the past year witnessed the consummation of many mergers and the growth and practice of various propagandas for the more efficient and, therefore, economical output of relative products. Concerning mergers, we are not disposed to credit those whose inspiration conceived them, as being imbued with the highest ideals and most patriotic motives, nor do we consider their flotation in such evidently wholesale fashion as an altogether public or national benefit proceeding. Consolidation, under stress of competition, may and does sometimes become necessary, but schemes whereby our industries are made financial footballs, do not assuredly tend to that stability of employment on which hinges the employes' greatest efficiency, and consequently our National ability to successfully hold a prominent place in the markets of the world. The unifying and reduction of administration expenses is, of course, a reasonable excuse for such a line of action, but we are not disposed to believe that the advantage so gained is in any way commensurate with the widespread and generally deleterious effects produced. A cessation of the merger fever has been distinctly noticable of late, due no doubt to some more or less unsuccessful realizations, and its resumption should be so carefully considered in the coming time, that nothing short of strict necessity will revive this dangerous plaything. A larger pride, with regard to a high place for excellence of product among the old established manufacturing nations of the world, and a lesser concern for stock market effects, is an absolutely undeniable requirement of industrial greatness and labor content of this or any other country.

Notwithstanding civic jealousies as evidenced in the upbuilding of the leading cities of the Dominion, in spite of the vested interests opposed, and independent of their influence in catching votes by either political party, there is little room for doubt that the Welland and Georgian Bay Canal Schemes will go forward to successful completion at no distant date, and present indications are that requirements will be ahead of the date of service available.

Problems, arising from the demands of organized labor, touching technical and industrial education and training, workmen's compensation, etc., are, so to speak, ripening for solution, and will demand wisely considerate handling together with a mutual sacrifice of cherished, yet mayhap, untenable principles.

FOUNDRY PRACTICE AND EQUIPMENT

Practical Articles for Canadian Foundrymen and Pattern Makers, and News of Foundrymen's and Allied Associations. Contributions Invited.

MOLDING A BED PLATE 19 FEET LONG.

By John H. Eastham.

MOST jobbing molders, who have been employed in small foundries where heavy work is done, are aware of the difficulties encountered in the successful handling of large pieces. Insufficient lifting facilities, coupled with lack of working space and bad light, put the foreman up against problems which take not a little solving before a casting is safely in the machine shop or shipped to the outside customer.

In a shop, which could not have been laid out worse, even by intent, the order was received for an oil engine bedplate measuring 19 feet over all; the general design of the pattern being shown in plan and side views, Fig. 1. We had a wheezy, old, hand-operated traveler, which, when new in a distant past, had been certified to carry three tons; also, a jib crane, hand operated, and which would carry about seven tons, if all the men in the shop and neighborhood crowded around to hoist, and to "pull her round" by the long chain attached to the end of the jib for this purpose. We had not a cope flask large enough to cover the job, and lift out the inside in the usual way. Again, if we had rammed-up two copes with a sloping parting between, we would have been prevented by the shape of the foundry from turning them over to receive the necessary finishing.

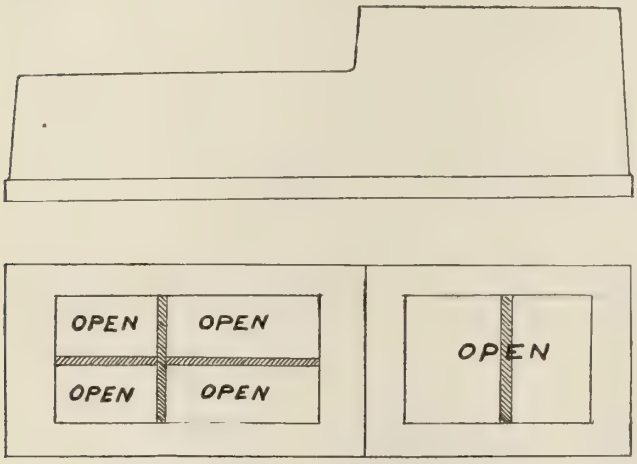

Fig. 1.—Molding a 19 ft. Bed-Plate.

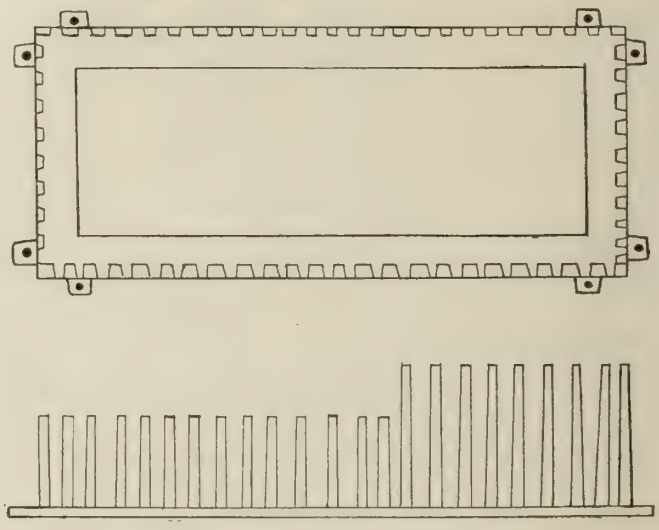

Fig. 2.—Molding a 19 ft. Bed-Plate.

After a little consideration, a plate to lift away the outside, as shown at Fig. 2, was cast; a hole six inches below the full depth of the pattern being afterwards dug out. A cinder bottom was laid over its full area, and a hard bed swept off four inches above the cinders. The pattern was laid on this, and a parting made around the outside; the plate already mentioned being lowered to place, over and embracing the pattern. After ramming the first outside course, 4 ingates, of sufficient length to clear the ends of the plate by several inches, were bedded in, two on each end of the pattern. The ramming of both cheek and core were proceeded with simultaneously, the skeleton design of the pattern making this possible. Another advantage consisted in the pattern being kept to shape without packing or wedging. The core being now securely staked, the corners suitably ironed, and the cheek plate rammed-up to its full depth, a parting was then made, and the lower or long end of the pattern and joint covered with stiff loam; the prodded plate "A," Fig. 3, being stamped on

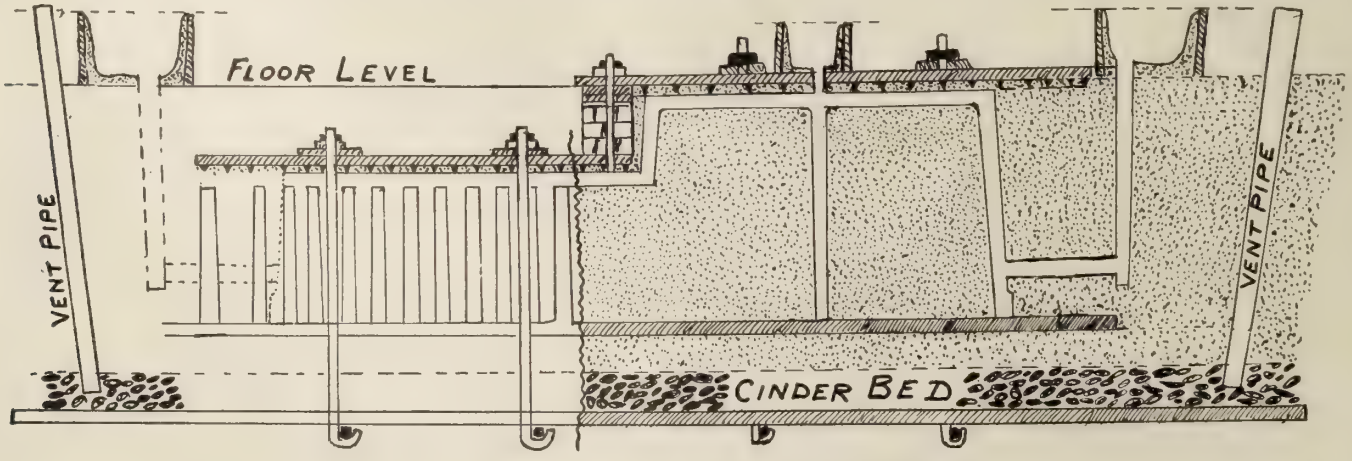

Fig. 4.—Molding a 19 ft. Bed-Plate—the Finished Mold.

this. After the upright face of the pedestal stand or high end of the pattern was jointed and the sides lined-up with wet parting sand, a course of brickwork was built on the plate "A," to the full height of the pattern, and stuffed-in with loam; the narrow plate, "B," Fig. 3, being laid on this and bolted to the plate "A" by the eyes and lugs indicated The top joint was next covered with parting sand; one inch of loam being spread over the whole top surface, and the crown plate "C" Fig. 3, stamped to place. In order to give the loam plates and brickwork time to "set," the outside of the cheek plate was dug away its full depth to allow of removal, and

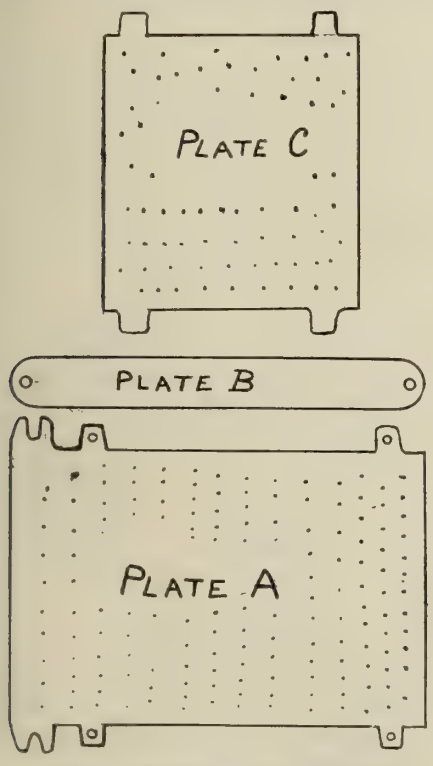

Fig. 3.—Molding a 19 ft. Bed-Plate.

the cheek staked at its four corners. The crown plate "C" was hoisted from the pattern, turned over, daubed-up where needed, and placed on the stove car; the process being repeated in the case of plates A, B, and brickwork combined. With the pattern seat strickled out to its correct thickness, and the core vented all over, down to the cinder bed, the cheek was hoisted away, and lowered on logs a little above the foundry floor, to permit the necessary finishing. The pattern was then drawn, the core finished, together with the jagged lift around the edge of the cheek plate, the company's nameplate stamped on each side of the mold, the whole plumbago blackened, and the cheek plate lowered again to place. The four ingates having been drawn outwards, and the upright runner pins placed exactly to their ends, the base of each runner was packed up by cake cores to avoid "ramming in."

The cope plate A with brickwork and plate B attached, and previously finished and blackwashed, was now applied, and being found accurate, the crown plate C was lowered to place. The whole mold was next bolted down to a permanent grating in the floor, Fig. 4, the outside rammed-up to floor level, the runner and riser boxes lined up, and the job successfully cast. A repeat order two weeks later, more than justified the small outlay on rigging.

THE LAYOUT AND PATTERNMAKING OF GEARS.

D. O. Barrett, B.Sc.

THE following article is not intended as a scientific treatise on the subject of gearing, but is for the benefit of the practical man, giving the details of laying-out the shape of the tooth and the method of making the patterns, so that the shape of the tooth shall be accurately retained. A general knowledge of the terms common to the subject is presupposed.

The methods here shown were used by the author in the manufacture of gears for several traction engines and commend themselves because of their low first cost, and also because each tooth is an exact duplicate of the others; an impossibility where the shapes are worked out by hand.

Laying-Out the Tooth Curve.

Fig. 1 shows the method of laying out the tooth curve. This is obtained by using Grant's Odontograph. The accompanying table was taken from the catalog of the Grant Gear Co. and gives the necessary constants for the various numbers of teeth. To make the method more concrete, a gear of 30 teeth and 2 inch circular pitch has been chosen. The pitch diameter for this will be $2 \times 30 \div 3.1416$ or 19.098 inches. The pitch circle may now be laid out and the teeth stepped off. To allow clearance

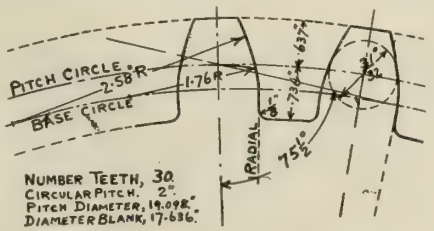

Fig. 1.—Method of laying-out tooth curve.

between the teeth, the thickness of the tooth itself was made 31-32 inches, which would give a clearance of 1-16 inches between the teeth of the intermeshing gears.

The next values to be obtained are the height above the pitch circle and the depth below, spoken of as the addendum and the dedendum, respectively. The addendum is equal to the circular pitch multiplied by 0.3183, or, in this case, equals $2 \times 0.3183 = 0.637$ inches. Now the dedendum is equal to the addendum plus the clearance at the bottom of the tooth, this being 0.05 of the circular pitch so that the dedendum is equal to the circular pitch multiplied by 0.3683 or, $2 \times 0.3683 = 0.736$. The outside diameter of the gear will be the pitch diameter plus twice the addendum or $19.098 + 2 \times 0.637 = 20.372$. The diameter of the blank or the diameter at the bottom of the tooth will be the pitch diameter less twice the dedendum or $19.098 - 2 \times 0.736 = 17.626$ This diameter at the bottom of the tooth will be used when the blank on which the teeth are fastened is turned up.

The circles for the top and bottom of the teeth should now be drawn in their proper positions. From the point where one of the tooth centre lines intersects the pitch circle draw a line making an angle of 75½ degrees to the centre line or making an angle of 14½ degrees to

Grant's Odontograph.

the tangent at that point. This line represents the line of pressure or the angle at which the tooth of one gear presses against the corresponding tooth of its mate. For this reason this style of tooth is called the 14½ degree involute

lute, the curve being of the involute form. A circle should now be drawn just touching this 14½ degree line or, in other words, just tangent to it. This circle is called the base circle and its diameter may be obtained accurately by multiplying the pitch diameter by 0.968 which is the cosine of 14½ degrees.

The diameter of the base circle will then be 19.098 × 0.968 = 18.497 inches.

Referring now to the table we find it contains constants for two values, the face radius and the flank radius which are to be multiplied by the circular pitch. For 30 teeth these constants are 1.29 and 0.88 which multiplied by 2 gives 2.58 and 1.76 respectively. Having marked off the width of the tooth

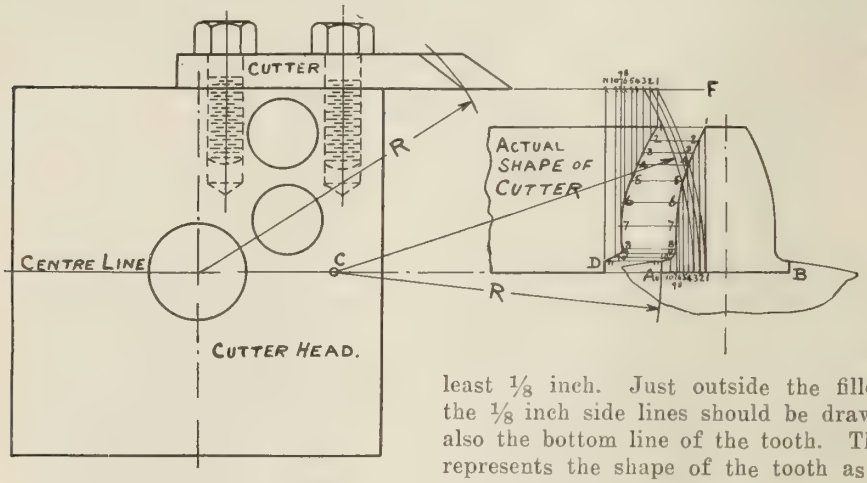

Fig. 2.—Development of cutter.

on the pitch circles, arcs should be drawn through these points, outward with a radius of 2.58 and inward with a radius of 1.76, the centres of these arcs being on the base circle. The flank of the tooth should be drawn radially with a line tangent to the inner arc. A fillet should join the tooth curve proper and the circle at the bottom of the tooth. In this case it was made ⅛ inch.

The following formulas have now been used:—

$$\text{Pitch diameter} = \frac{\text{Circular Pitch} \times \text{No. of Teeth}}{3.1416}$$

Addendum=Circular Pitch×0.3183.
Dedendum=Circular Pitch×0.3683.
Total Height of Tooth = Addendum + Dedendum.
Outside Diameter = Pitch Diam. + Twice Addendum.
Blank Diameter = Pitch Diam. — Twice Dedendum.
Base Circle = Pitch Diameter × 0.968 inches.

There are several methods of making the pattern for a spur gear. One method is to turn up a blank to the outside diameter of the gear and then lay out the teeth on each side, cutting or sawing them out, and then finishing by hand. This is rather tedious and the shape of the teeth will vary considerably. The teeth may also be cut to a templet and then sandpapered and fastened to the blank. In the method about to be described the teeth are machine-cut, all teeth being of exactly the same profile.

The cutter head is of cast iron and may be bored to fit the arbor of a table saw. The removable plate of the saw table is replaced with a wooden one and the cutter head raised up through the board cutting a space for itself. In this case the head was 4 inches square and 1½ inches thick.

The tooth should now be laid out by the method just described. In cutting the teeth the fillet at the sides will be integral with the tooth itself, and the teeth should be set into the blank at least ⅛ inch. Just outside the fillets the ⅛ inch side lines should be drawn, also the bottom line of the tooth. This represents the shape of the tooth as it will be set into the blank.

Now extend the bottom line and at one side draw the cutter head using the extended line as a centre line. The cutter will be made of tooth steel of any desired thickness and may easily be fastened to the head by means of two cap screws. Were the cutter placed radial, it would then be of the same shape as the tooth but this would not give a cutting edge so that it is necessary to place the cutter on the edge of the block striking the pattern at an angle. It is thus necessary to develop or lay out a curve which at this angle

Fig. 3.—Tooth strips, after being cut.

will give a tooth of the predetermined shape. To determine the position of the cutter let us assume that the part which cuts the straight side of the tooth as at "A," is set ¾ inch from one side of the head. Laying this out, take the distance from this point to the centre as shown at "E." With this length strike back from the point "A," on the centre line intersecting at "C." This is the centre from which all arcs will be drawn.

Now choose any number of points along the tooth curve, and for convenience in locating, number them as "1, 2, 3," etc., and project these down upon the centre line, numbering there to correspond. From centre "C" draw arcs from all these points to the face of the cutter, extended, as at "F" numbering as before. From these points project downward, intersecting lines drawn through the original points parallel to the centre line. To be specific, project down, for instance, from point "2," also draw a line from point "2" on the tooth shape parallel to the centre line and the intersection of these two lines will give a point on the cutter.

Doing this for all the points and drawing a curve through same gives the shape of the cutter. The more points chosen the more accurate will be the cutting shape. The width of the cutter will, of course, be the same as the height of the tooth.

The cutter must be backed off to give a proper cutting edge and to allow for clearance and, after hardening, is ready for use.

In laying out the cutter, difficulty will be experienced, as for instance, at points "7" and "8," the lines being so close, makes it rather hard to distinguish between them. For this reason the first tooth cut should be compared with the original shape and any slight errors may be corrected by honing the cutter.

The material for the teeth may be cut in any desired lengths and should be made in thickness equal to "AB," while the width should be greater than twice the total height of the tooth. A guide should be placed on the saw table just in line with the side of the cutter corresponding to "AB" and the head then brought up through the table until the point "D" of the cutter just touches the face of the wood, the piece may then be turned over and the teeth will come the right thickness without further adjustment.

The strips, after being cut, will appear as in Fig. 3. They may now be sawed along lines "aa" and "bb" which will separate the two strips of teeth. The projecting parts serve to keep the strips flat while sawing. The teeth can now be cut to the desired length and are ready for attaching to the blank.

THE CONVERTER IN THE FOUNDRY.

By E. B. Gilmour, Toronto.

IN any process for the successful production of steel, two conditions are necessary—perfect and absolute control over quality of material, and regularity of production. To fulfill these, designers of the converter came forward

and proclaimed it as the panacea of all evils in the production of steel castings. Further, they stated that any intelligent man could be taught to handle a converter steel plant in from 2 to 3 weeks' training under an expert, for it only required the proper mixture charged into the cupola, drawn off with a certain analysis, poured into the converter, and the "blow" started, in order to have in 15 minutes, two tons of steel ready to receive the additions deemed necessary to bring it to a desired specification.

The above ideas having been spread broadcast, many were encouraged to enter the steel converter business, and as a result, failure and condemnation of the system was the reward of all, except a few who had the money and stamina behind them to get down to certain hard facts that had to be faced.

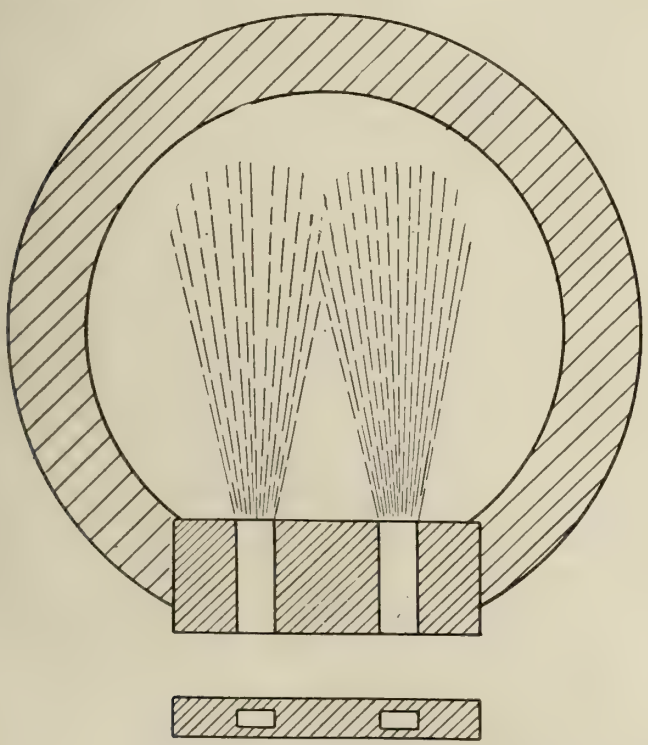

Fig. 1.—System of Tuyerage for Converter Blast.

The procedure adopted was to hire a college graduate as chemist, put him in charge of the cupola and converter at a salary of $40 to $50 per month, in the expectation, not, however, realized, that steel castings would be produced at 3 cents per pound, and sold at 4 or 5 cents per pound. I have in mind the starting of a company which figured as stated. They had visited some of the successful concerns, and thought they had only to go home and do likewise. They tried to take the steel from the converter in bull shanks, as you would cast iron from the cupola, but to their surprise, failure of every description appeared, and before long they were out of the steel business. Another company, with which I am familiar, have now got over the hard knocks of experience and are running from 15 to 20 heats per day in a 2-ton converter. A heat is melted, blown and poured every 25 minutes after the first, and this at an average loss of 15 per cent. of metal handled, pouring with a tea-pot spout ladle and also into bull shanks, to cast regular snap work. In this plant they had a practical foundryman at the head and an expert chemist with efficient assistant in charge of the cupola and the converter.

Varieties of Converter.

There have been many varieties of converter put on the market, although all practically embody the same ideas. The differences lie in the tuyere arrangement. This being the vital part, any deviation from the correct style resulted in a proportional amount of trouble. Fig. 1 is a system of tuyerage with only two openings for the blast to enter. This caused the blast to be concentrated in two portions of the surface of the metal, as shown, and during the "blow" it formed a double eddy by which the slag whirled around the converter next to the lining and dropped over the tuyeres, practically closing them up. As a consequence, every little while the blast had to be stopped to clear them. Under such circumstances, the blowing period was, of course, increased, the time taken being from 40 to 45 minutes instead of from 12 to 15 minutes. Extra power was also consumed, and in addition, insufficiently hot metal resulted.

Fig. 2 is another system of tuyerage, constructed with a number of small holes about $\frac{7}{8}$ inch diameter, in such manner as to distribute the blast over the whole surface of the metal in the converter, thereby securing a regular and steady boil, with hotter metal of more uniform kind.

In charging the cupola, one should aim to use as much steel scrap as possible so as to reduce the cost of production. On account of the steel being low in carbon, it will, in passing through the cupola, absorb that element from the fuel and become so saturated that you will only have to supply silicon in the form of pig iron to reduce the total loss of metal in the whole melt. The amount of silicon required in the mixture should not be over 2 per cent., and with experience in blowing, it can be reduced to an even greater extent. It is desirable to keep the sulphur and phosphorus as low as possible, and in order to get rid of the former some converter people have tried to melt the iron with oil, instead of coke. The introduction of the electric method bids fair to revolutionize the steel business, by taking the place of the crucible and converter, especially where cheap power is obtainable.

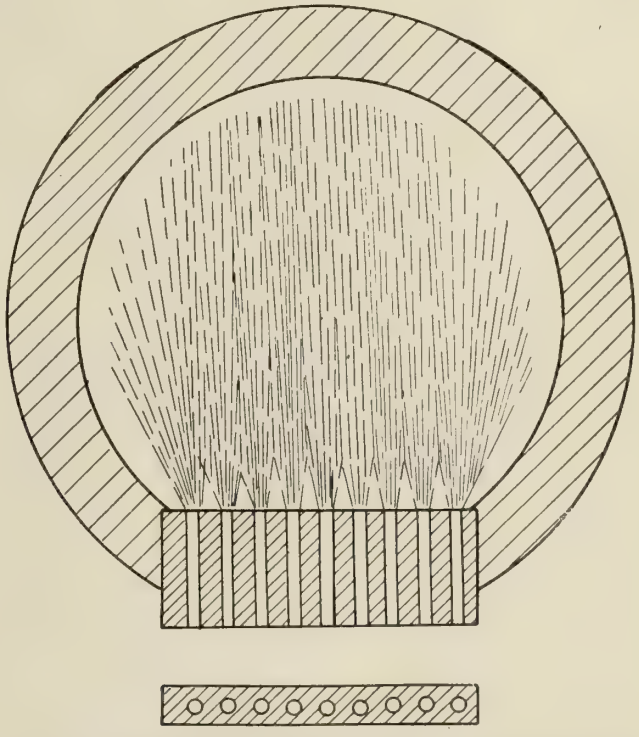

Fig. 2.—System of Tuyerage for Converter Blast.

Molds for steel castings, especially those of the latter which have to be machined, are nearly all made in dry sand. If machining is not required, they may be cast in green sand, but under the skin small blow holes are much in evidence. The final additions to the converter are made by various means, but preferably in a small cupola. Some people, however, use a crucible.

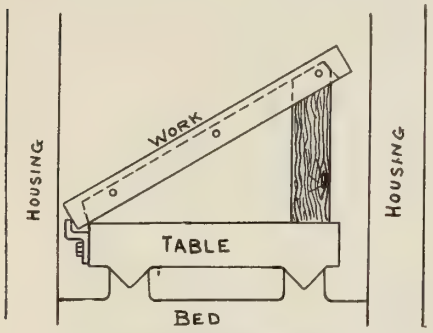
Unique Ways of Doing Things in the Machine Shop. Readers' Opinions Concerning Shop Practice. Data for Machinists. Contributions paid for.

SPLITTING OLD HOSE BAGS.

By W. B. Crockett.

THE device here illustrated is a small motor-driven shear specially designed for splitting worn-out hose-bags and removing the wire, in order to recover the scrap value of the rubber. One end of the hose-bag is placed over the nose B of the moving blade-plate A, fig. 1, and as it is cut by the blades D and E, it divides and passes on either side of the neck C, as may be clearly



Facing Wide Castings.

seen in fig. 2. The hose is fed forward by hand and split from end to end. It is then reversed and fed through a second time, splitting it on the opposite side and so dividing it into halves. The two unwired ends of the hose are next cut off, after which the outer covering over the wire is easily stripped, and the wire drops out.

Fig. 1 shows the construction of the machine, while from fig. 2 a clear idea of its operation may be obtained. It will be noted that the gears are covered in with a neat casing. Railway men will, of course, be well acquainted with the meaning of the term "hose-bag," but for the benefit of other readers it may be as well to explain that a hose-bag forms the flexible connection between the water-valve on the tender and the injector suction pipe on the locomotive, and consists of a tube of rubber and duck, stiffened with a wire coil, except for a short distance at each end.

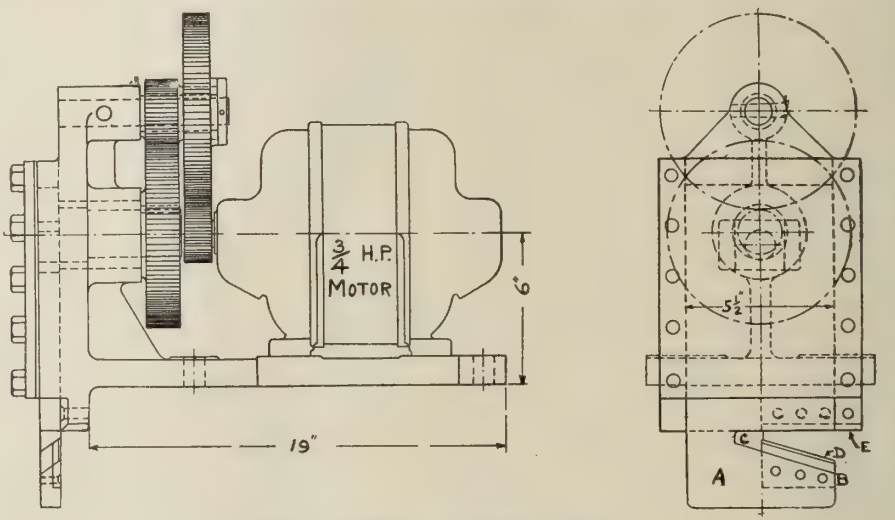


Fig. 1—Hose Bag Splitting Machine.

FACING WIDE CASTINGS.

By Donald A. Hampson.

A MANUFACTURER of tinware sent us a number of cast-iron plates to be faced-off on the planer. When they arrived, it was found that they were too wide by ½ inch to pass between the housings of the planer. At the ensuing consultation, permission was given to take ¼-inch full off the ribs on each side, it being left with us to do the job in the cheapest way possible. Chipping was instantly discarded as being too laborious and costly, and on further consideration the necessity for reducing the plates' width before planing was overcome by setting them up as shown. The planer had at one time been drilled throughout the whole length of the table for side clamps, and these holes we now proposed to use. To that end the blacksmith made a pair of Z pieces out of ⅝ x 3 inch stock. These were bolted to one side of the table, at points near the ends of the position which the plates were to occupy. This and the manner of setting the work is shown in the illustration.

The work was supported at an angle of approximately 30 degrees by lengths of hardwood blocking, and by the Z pieces, the ribs across the ends resting at one point on the table. Holes for finger clamps had been drilled and the thrust of the cut was provided for by posts and an angle plate. It only remained to set over the head 30 degrees and throw in the down feed.

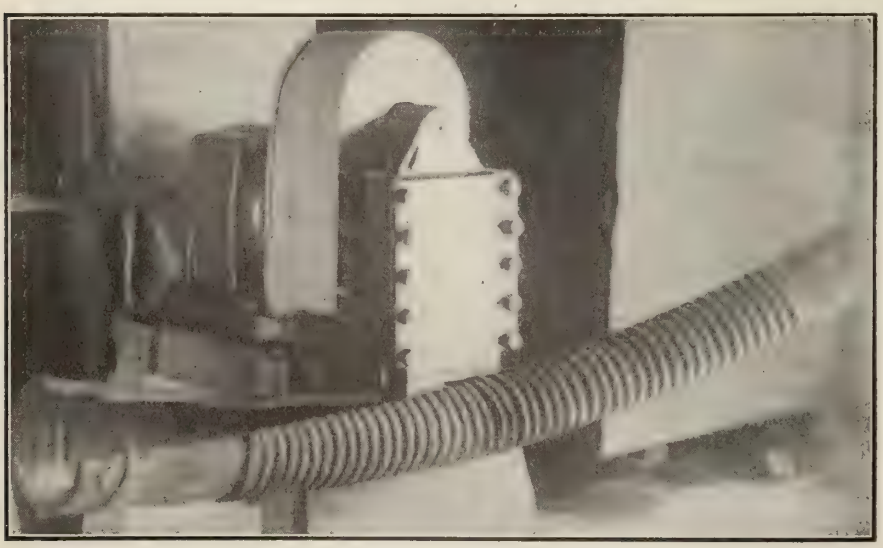

Fig. 2 Hose Bag Splitting Machine.

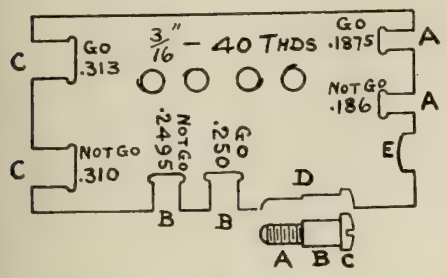
A SCREW GAUGE.

By Chas. Hattenberger.

THE type of gauge here shown has proved very useful to those engaged in making large numbers of screws, pins or almost any form of screw-machine work.

The example here illustrated is used for gauging the 3-16-inch screw shown.

It is made from a flat steel plate and has three pairs of slots in it, A.A., B.B. and C.C., which form limit gauges for the corresponding diameters of the screw. D. is a profile gauge, while E gauges the radius of the screwhead. The



A screw Gauge.

holes shown are for gauging the thread and are tapped out with a master tap. If they shrink during the hardening process, it is best to turn-up and thread a piece of copper in the lathe chuck, and use this as a lap with fine emery flour and oil. If one of these holes should wear large through use, plug it up to prevent mistakes.

In making this gauge cold-drawn machinery steel may be used if facilities for carbonizing are at hand. Use stock $\frac{1}{8}$-inch thick for screws up to 3-16-inch diameter, and 3-16-inch thick for screws up to $\frac{3}{8}$-inch diameter. This type of gauge is not well suited to screws over $\frac{3}{8}$-inch diameter. The snap gauge openings A.A., B.B., C.C., are made .010 inch small, and afterwards ground and lapped to size. The profile gauges, D and E, are made to size, but should any change take place in the hardening, they are lapped and oil-stoned back to the correct shape.

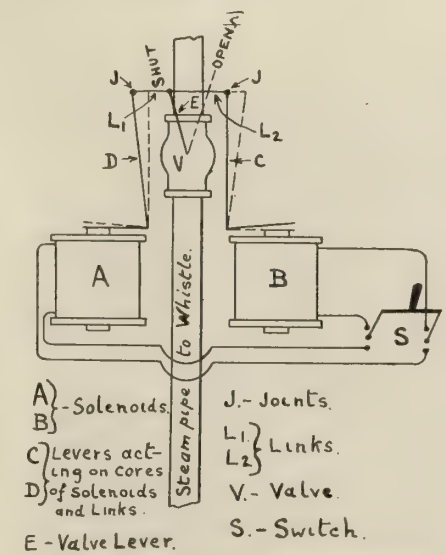
BLOWING THE WORKS WHISTLE.

By John E. Davies.

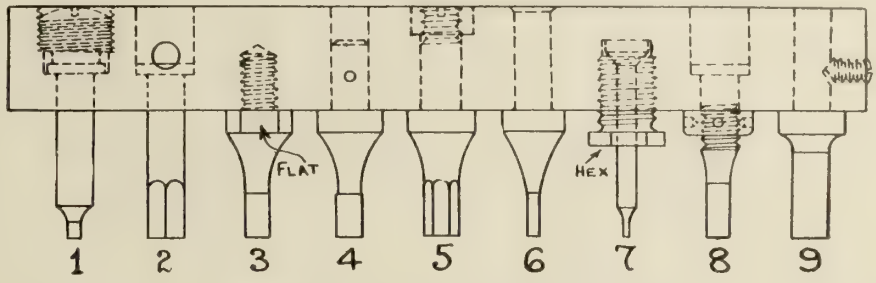
IN the accompanying illustration is shown a device for "blowing the works whistle" from the office. The steam pipe leading to the whistle must be brought to a convenient place in the wall. Using an inch pipe we connect to it an easy-working but steam-tight valve V, which will, with a turn of about 60 degrees, open full. A lever, E, is attached to valve V to operate same, and to this lever E are attached the links L1 and L2. These are connected to bell crank levers D and C, and are acted upon by the solenoids A and B.

In the illustration, the valve is shut. Closing the upper circuit through solenoid A, the core, becoming magnetized, attracts the short leg of the bell crank lever C, and moves the long leg, link L2 and lever E to the position shown by the dotted lines, thereby opening the valve V and blowing whistle. Further, link L1, and bell crank lever D, are put into the position shown by the dotted lines, thus lifting the short leg D off the core of solenoid B.

To close the valve, open the upper circuit and close the lower. This sends current through solenoid B and reverses the process. When valve is closed, open the switch S.



Device for Blowing the Works Whistle.

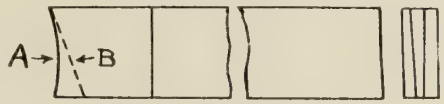


Methods of Securing Punches in Holders.

GRINDING A CUT-OFF TOOL.

By C. T. R.

WHEN cutting off pieces of steel in the lathe the operator is often troubled by the tool digging in and snapping off. This difficulty may be overcome by grinding the tool as at A in the illustration, and making the



Grinding a cut-off tool.

radius larger than the radius of the piece being cut off. By grinding in this manner the tool is made much stronger than when ground in the usual way shown by the dotted line at B.

SECURING PUNCHES IN HOLDER.

THE accompanying cut shows nine different methods of securing punches in a punch holder. In No. 1 the punch is inserted from the top and the thrust taken by the screw shown. No. 2 is also inserted from the top, a hole being drilled through the holder at right angles to the punch, and a pin, with a flat filed on it, a few thousandths of an inch taper, is driven in to bear on the top of the punch. No. 3 is merely screwed into the holder, the collar being provided with two flats to fit a spanner. No. 4 is held in place by a standard taper pin; but this method is not to be recommended. In No. 5 the punch is held by a round nut having a slot across its centre by means of which it is tightened.

The punch shown in No. 6 is made a snug fit in the holder, and is then riveted over at the top. This method holds the punch securely, but has obvious disadvantages when it becomes necessary to remove it. Punch No. 7 has a countersunk head and is held in place by a long nut bored to fit. No. 8 is inserted from the top, being threaded for a portion of its length and drawn up tight by a round lock nut. No. 9 is held in place by a headless set screw, the point of which fits into an angular slot across the punch shank. The screw point should engage the slot a little above the centre in order to draw the punch up tight.

CUTTING A QUADRUPLE THREAD.

By A. Leonard Marshall.

I WAS recently called upon to cut threads in a nut to match a 1-inch diameter screw, having a quadruple thread of 1-inch lead. Instead of dividing the face plate into four parts, I selected a lathe having a lead screw with 4 threads per inch, and, of course, geared same to the spindle with 4 to 1 gears. After setting the tool near the edge of the nut, and marking the bed of the lathe at the back of the carriage, I closed the split nut and took a cut. I next marked the lathe bed in front of the carriage, and while the lathe was at a standstill, I moved the carriage $\frac{1}{4}$-inch toward and past the back mark, closed the nut again and took another cut, being careful to stop exactly at the front mark when the tool was

through. Repeating the operation, I brought the carriage ½-inch toward and past the back mark, then ¾-inch, and at the next and last movement picked up the first cut.

The method adopted gave me a chance to try in the screw as the threads neared completion, and also ensured the pitch being as accurate as that of the lead screw.

RELIEVING ATTACHMENTS FOR THE LATHE.

By A. D. Campbell, Hamilton.

THE accompanying half-tone shows a relieving attachment for a 14-inch lathe which has proved very effective on all kinds of taps and special shaped

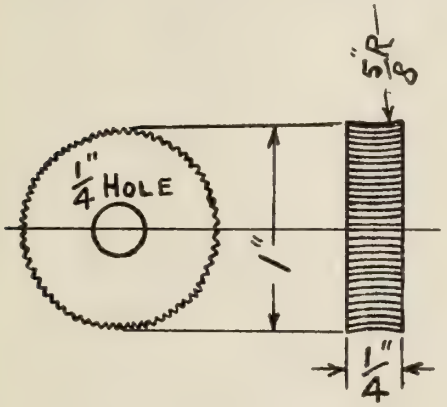


Fig. 1.—Cutting Teeth on Knurls.

milling cutters. The face gear being the most solid gear on the machine, power is taken from it through a 3 to 1 ratio of gearing. The bracket bolted to the lathe bed carries a radius arm to which are attached suitable train gears for the number of flutes in the work. The regular train gears are used. This device will work any even number of flutes from 2 to 16. The tool block slide is held against the cam by a stiff spring, the tension of which may be adjusted by means of a screw. The whole slide can be swivelled around, 30 degrees, either

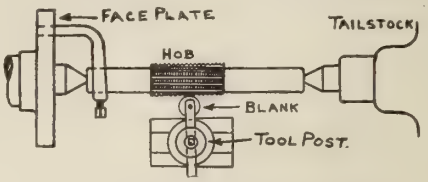

Fig. 3.—Cutting Teeth on Knurls.

way. Four cams have been provided: 1-64, 1-32, 1-16 and 1-8 inch.

Since the photograph was taken, a bracket has been fitted on the left hand side of the swivel slide. This carries a shaft, with a pair of bevel gears, one of which, on the cam shaft, replaces the swivel joint fork shown. The latter was transferred to the other end of the bracket shaft, and connected with the telescoping shaft. Relieving the tooth side of square-threaded taps has been greatly facilitated.

CUTTING TEETH ON KNURLS.

By Charles Hattenberger.

SOME time ago I had a job to make about sixty knurls as shown in fig. 1. They required to be approximately 1 inch diameter, and to have 80 degree teeth, 1-32 inch apart. My first thought was to mill them, but this would have proved too tiresome, so I concluded to hob them. I made a hob 1¼ inches diameter, 32 threads per inch, and having twelve flutes 3-16 inch wide.

The fixture shown in fig. 2, is made of soft machinery steel, carbonized, and the pin with the knurled head is made of tool steel. This fixture is held in the lathe tool-post, and the blanks, after being turned up, are inserted in the slot and held in place by the pin. Care must be taken when setting, that the slot and lathe centres are in line, and that the blank rotates freely in the slot. With the lathe carriage stationary, the blank is gradually fed into the hob until the teeth are fully developed. Fig.3 shows the arrangement.

LATHE TOOL FOR TURNING HAND WHEELS.

By L. C. D.

THE tool here shown is handy for turning up outside radii, such as the rims of handwheels and similar ob-

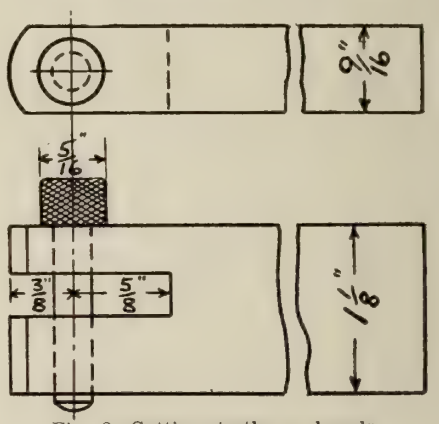

Fig. 2—Cutting teeth on knurls.

jects. As may be seen in Fig. 1, it consists of a ⅝ inch diameter piece of tool steel, with six cutting edges ground in its circumference, each to a different radius. In grinding, 5 to 7

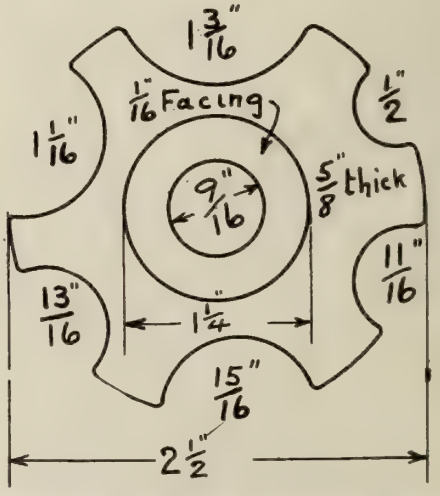

Fig. 1—Tool for Turning Handwheel Rims.

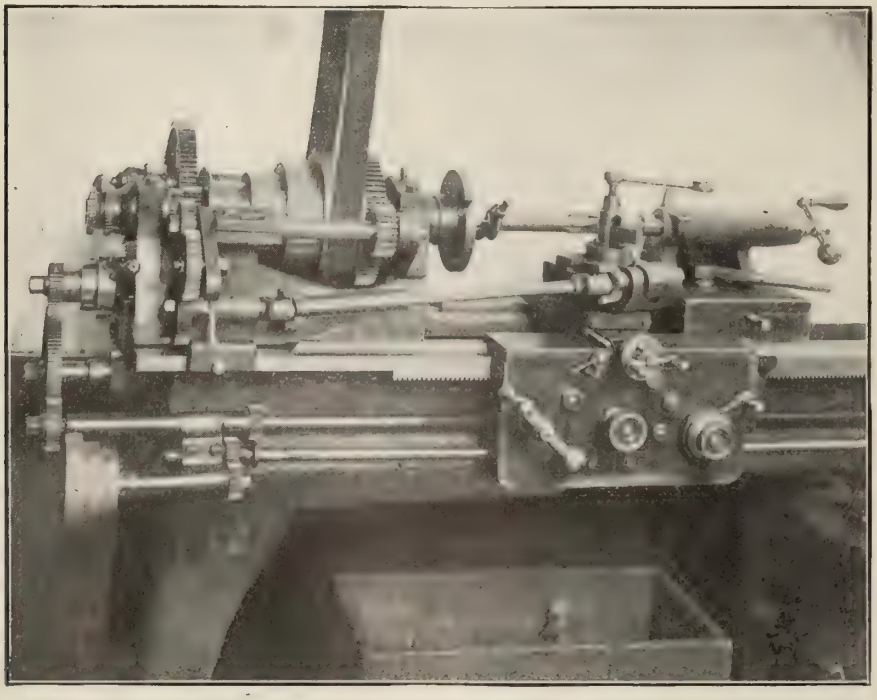
degs. of clearance is given. The sizes given, which are stamped on the tool, show the diameter of the finished work and not the radius of the cutter. Fig.



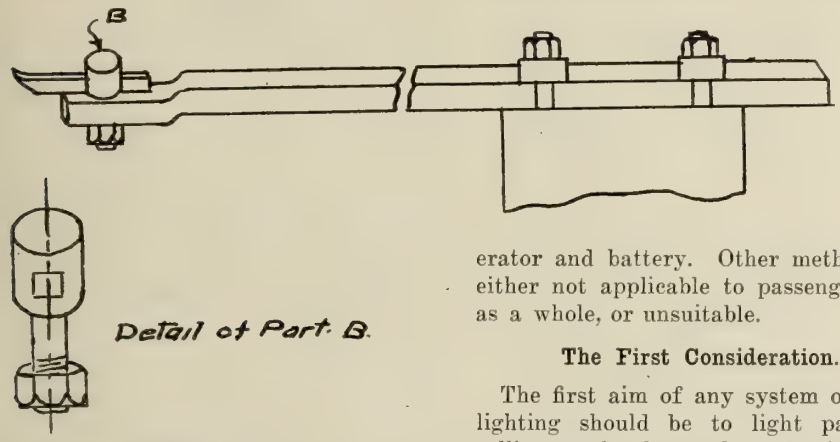
Relieving Attachment for the Lathe.

2 illustrates the spring tool-holder used in connection with the device. The tool is adjusted with the required cutting edge towards the front, and then clamped in the holder by means of the bolt through its centre.

A HANDY TURNING TOOL.

By A. L. Marshall.

THE tool here shown has proved very useful in a large lathe for turning work that will not swing over the carriage, or for boring large holes. The bar is drilled and counterbored to take the



A Handy Turning Tool.

bolt B, the counterbore being deep enough to prevent the shoulder of B from resting on the bottom when the tool is clamped in place. The bolt holds the tool securely at any desired angle. The bar is made from heavy square stock, the end being set down to suit height of the lathe centres.

ELECTRIC LIGHTING OF TRAINS.*

By Roger T. Smith, B.Sc.

THE method of train-lighting considered is that in partial use on the Great Western Railway, where axle-driven dynamos and batteries controlled by an automatic regulator are installed on brake-vehicles only. The lamps throughout the train are supplied from these equipments, which work in parallel with each other, the brake-vehicle equipments and the lamp wiring in the coaches dependent on them being connected electrically by through wiring coupled between coaches. There is, consequently, an appreciable reduction in initial cost and upkeep of plant, and, what is of chief importance from the railway point of view, increased reliability. Mr. William Langdon's paper, read before the institution in 1891, describes his, the first attempt to light electrically passenger rolling stock in general, in place of lighting set or block trains which were never broken up in traffic. Mr. Langdon's final method provided one axle-driven dynamo in the block part of a main line train, and a battery on each of the other coaches. All coaches were electrically coupled, and when disconnected, the lighting of each coach was continued during its branch journey by means of the charged battery. For any method of electric train-lighting applicable to all passenger rolling stock, the alternatives are either some such method as proposed by Mr. Langdon, or that every coach is "self-lit," that is to say, provided with its own axle-driven generator and battery. Other methods are either not applicable to passenger-stock as a whole, or unsuitable.

*Abstract of paper read before the Institution of Civil Engineers, London, Eng., Nov., 1911.

The First Consideration.

The first aim of any system of train-lighting should be to light passenger rolling stock adequately and with reliability. Measurement and experience lead to the provision of an illumination, measured on a horizontal plane at eye-level, of 2 foot-candles in third class, and 2½ foot candles in first-class compartments. Glare or dazzle can be minimized if not entirely prevented by keeping lamps out of the line of sight; by providing a white background behind the glowing filament, or by reducing the intrinsic brilliancy of the latter by enclosing the lamp in a diffusing or Holophane globe; the latter at the same time improving distribution. The tungsten train-lighting glow-lamp now replaces

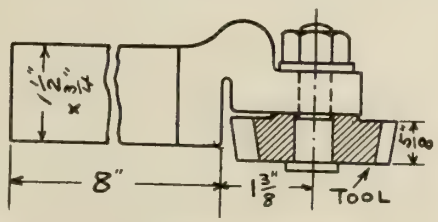


Fig. 2—Tool for Turning Handwheel Rims.

the carbon glow-lamp, its present most economical efficiency being 1.3 watt per candle. On the average, tungsten glow-lamps, with a useful life of 850 hours, have to be changed only once a year in the electrically-lit coaches on the Great Western Railway, where lamp-voltage is regulated within plus or minus 2½ per cent.

Any axle-driven system must, in the first place, provide a lead-cell or other accumulator, so that the lamps are lit whether the train is standing or moving throughout its range of speed. In order to draw proper attention to the importance of the accumulator in train-lighting, it is both convenient and useful to look upon the accumulator as the essential element and on the dynamo as a device for making the output of the former continuous throughout the hours of lighting. As typifying the accumulator, the lead cell alone is considered. The two extremes, among methods of charging lead cells, are charging at constant voltage and charging at constant current, but a method of charging which combines the advantages of both extremes, while avoiding their disadvantages, is recommended, the charge being completely under the control of an automatic regulator set to give the proper compromise. The arrangement consists in starting with a heavy charge and gradually reducing it, until, after proper gasing has taken place so as to mix the electrolyte, the charge is stopped when the cells are full, or the battery is left floating on the load while lights are on. Automatic regulation is necessary to secure a long and healthy life for the lead cell, and to reduce maintenance, it is essential. When properly arranged, 10 per cent. per annum of the initial cost of the whole cell will provide for both maintenance and renewals of the plates and boxes.

Automatic Regulation.

The train-lighting dynamo is of secondary interest as compared with the battery, the essential element being some means of keeping the voltage constant at all speeds while permitting of its automatic variation by the regulator when required. The suspension and driving of the dynamo and the reduction of belt losses and renewals are among the chief factors in success. The automatic cut-in cut-out switch for connecting or disconnecting the dynamo from the battery should be actuated electrically, since the voltage of the latter may vary 25 per cent. from that of the former at any given speed. It is desirable that this switch should also act as an instantaneous automatic reverse-current circuit-breaker. The problem of automatic regulation has not attracted the British inventor as compared with other inventors on both sides of the Atlantic. The functions of an ideal regulator, combining in one or two instruments, battery and lamp-voltage regulation, may be defined briefly as the following: First, it must control the lamp-voltage within plus or minus 2½ per cent. of the rated voltage of the lamps, and, within reasonable limits, must do so independently of lamp-load and entirely independently of battery-voltage. Secondly, when lamps

are off, the regulator must control the generator-field so as to provide the full output of the dynamo for charging an empty battery; and when lamps are on, the balance of the full output must be available for charging. As charging proceeds, the regulator must control the inherent regulation of the dynamo so that its voltage only rises sufficiently to give a diminishing charging current. Thirdly, with a fully charged battery and lamps off, the regulator should reduce the charging current to zero. Fourthly, with a fully charged battery and lamps on, the dynamo output must be adjusted to equal the lamp load, leaving the battery in a floating condition with current neither entering nor leaving it. The foregoing requirements can to-day be obtained combined in one piece of apparatus.

The Brake-Vehicle Method.

An experimental six-coach train lit on this method was run nearly continuously for two years in all sorts of traffic, varying from fast main-line services to slow, stopping, local services. Two brake-vehicles, equipped with 45-ampere dynamos, regulators, and 180-ampere batteries, light themselves and three dependents. A self-lit detachable coach completes the train. The Leitner system provided the only available apparatus able to meet the special conditions. All the equipments are in parallel, coupled by cables throughout the train, so provided. For the lighting circuits, the through wiring and method of coupling is arranged on the loop-positive system, one regulator controlling the lamp-voltage on each side of the loop. The same looped-positive brake-vehicle method has been applied to two trains running on South Wales services, to two new trains specially built for the Cunard boat service between Paddington and Fishguard, and to two new trains used for Birmingham local services; and it is being further applied.

The total annual cost of lighting a six-coach train on the looped-positive brake-vehicle method is as follows. The cost of the initial equipment would be $3,800, inclusive of all carriage-work charges. Adding working-costs, extra cost of locomotive-power — determined experimentally—and capital charges, the total annual cost becomes :—

Working costs	$225
Power to drive dynamos, 1½ per cent. on $4,375	65
Haulage of extra weight, 1.7 per cent. on $4,375	75
Interest on $3,800 at 4 per cent. ...	150
Reproduction of capital in 20 years at 3 per cent.	115
Total annual cost of lighting a six-coach train.....	$630

With regard to the safety of electric train-lighting, although at 22 volts an arc can be formed between any of the metals employed in train-lighting, this arc will not persist. Provided the ordinary precautions necessary with electric circuits are taken, and suitable fuses are used and properly maintained, it is believed that complete immunity from fire risks can be ensured.

HARDENING AND TEMPERING CARBON STEEL TOOLS.

By Frank Walker.

STEEL tools, used in the mechanical operations of turning, boring, punching, etc., are subjected to fit them for their several purposes to three general heat treatments or processes — forging, hardening and tempering; the two last being perhaps the most important through which they pass, and probably also the least understood by the average mechanic.

Carbon steel, properly treated, will be found, in nine cases out of ten, to answer all the requirements of the general or jobbing shop, and to be far more economical than the expensive high-speed alloy-steels from which best results are only to be obtained under conditions non-existent in the average machine shop. Carbon steel is the name given to a combination in various proportions of iron and carbon. There are also present, as impurities, other elements and metals, but carbon is the element which determines its characteristics and directly governs the hardening qualities. The amount of carbon present varies within certain limits from .5 to 2.2 per cent., and is known as the "carbon content" of the steel. Carbon steels are generally divided into two classes—the "unsaturated," in which the carbon content is less than .89 per cent., and the "super-saturated," in which the carbon content is greater than .89 per cent. The saturation point is fixed at .89 per cent.

Hardening and Tempering An Old Art.

Hardening and tempering have been practiced, with more or less success, from time immemorial, and some of the old sword blades to be seen in our museums, are splendid examples of the craft. At the same time their production determined no definite rules for performance or guidance, except, perhaps, a general one—that steel should always be hardened on a rising heat and at as low a temperature as possible. Careful experiments carried out during recent years have determined, without doubt, that the hardening process proceeds along certain definite lines and within certain definite limits, and these, if carefully adhered to, will always assure success. The old rule, already quoted, though very indefinite, will be found to agree closely with those which modern research has brought to light and taught.

To harden a piece of steel, it is not merely sufficient that it be heated and then suddenly cooled. In order to ensure certain and perfect results it is absolutely necessary that the right temperature be obtained, because inability to determine this, on the part of the operator, is the reason for so many failures in hardening. The temperature of the cooling medium is also subject to limitations.

The Temperature Factor.

In the process of heating there is a certain critical temperature easily determined by the proper means, at which steel will harden with the best results and with adsolute certainty. This, known as the "point of decalescence," is one of the most peculiar and least known characteristics of carbon steel. I will endeavor to give an elementary explanation of the phenomenon, and also of the manner in which its occurrence is demonstrated. In the bar of tool steel as received from the manufacturer, the carbon is not distributed equally throughout the mass, but is carried in a particular way; one atom of carbon allying itself with twenty-one atoms of iron and forming an alloy known as "pearlite." This "pearlite" is distributed through the bar in spots or islands surrounded by free carbonless iron called "ferrite." If heat be applied to the bar, its temperature will commence to rise and continue to do so until a certain point is reached, at which atomic changes take place within.

The "pearlite" becomes broken up, and its carbon content changes its nature and becomes "cementite" or hardening carbon, which enters into "solid solution" with the "ferrite." This readjustment is accompanied by two marked peculiarities, whose observation determines the exact period at which the change occurs. In the first place, the steel loses its power of attracting a magnet, and in the second, the temperature of the piece stands still, or even falls slightly, for quite an appreciable length of time, although heat be still applied. This is due to the chemical action having absorbed the added heat. After the change has been completed, the temperature of the piece again commences to rise, and will continue to do so proportionally.

Should the steel be now removed from the influence of heat and allowed to cool slowly, it will pass through another critical period called the "point of recalescence." This marks its return to the original atomic structure, and occurs at a lower temperature than the

point of "decalescence." At this stage the heat, absorbed by chemical work in the previous period, is again given off, and causes the falling temperature to remain stationary for a short time, or even to rise slightly, although the surroundings be much colder. At the same time the steel regains its power of magnetic attraction.

The accompanying diagram, copied from one taken with a registering pyrometer, clearly shows the two periods, and it must be understood that the second cannot take place unless the first has been passed. Now, as this point of "decalescence," which varies with the carbon content, marks the exact temperature at which the particular steel being treated will harden with the best results, and as no definite rules for it can be quoted by which the operator can be guided, it becomes necessary to determine this temperature by actual experiment. This can be done by connecting a registering pyrometer, several types of which are made, with a small gas, oil or electrically heated furnace. A small test piece from the steel to be hardened should be attached to the terminal of the pyrometer, the furnace brought up to a temperature of about 1,700 degs. F., and the test piece placed in it. The latter heats rapidly, and its temperature, as recorded by the instrument, will rise uniformily till the "decalescence" point is reached. A noticeable halt then takes place in the upward movement of the needle. The piece should now be quickly removed from the furnace and its color carefully noted, as showing the proper heat for hardening that particular steel. The experiment should be repeated and results compared to verify the record.

Should a pyrometer not be available, a very good substitute is a magnet. Again, the heat color of the "decalescence" point of a steel may be very accurately determined by the following means: Place a small mariners' compass on a wooden stand close to the fire or furnace in such manner that the heated piece can be swung close to the magnet in a plane parallel to the needle, that is, north and south. If using a blacksmith's forge, the piece should be heated in a muffle made from a piece of wrought iron pipe. Heat the piece slowly, withdraw and test it frequently with the compass, using for the purpose a pair of pliers made by bending a piece of strong copper wire. The heat at which the piece ceases to attract the needle is its "decalescent" point, and the color should be carefully noted as in the experiment with the pyrometer.

Color and Temperature.

Once the proper heat has been determined it is possible to successfully harden without fear of failure each and every tool made from that particular steel. The color of a heated piece is a fairly accurate guide to its temperature, and the following table gives approximately the value in deg. F. of the various heat colors: Faint red=950, dull red=1150, brilliant red=1350, cherry red= 1550, bright red= 1750, orange =2000, bright orange=2190, white= 2370.

I have endeavoured thus far to explain the principles which govern successful heating, but it must be remembered that success also depends upon the manner in which the steel is heated.

Manner of Heating.

When hardening steel, it should never be heated in direct contact with the fire. If a special furnace is not available, a muffle made, as explained already, from a piece of wrought iron pipe, should be placed in the fire, and brought to a bright red heat before the piece to be hardened is placed in it. The muffle should not be too large, but of just sufficient size to enable entry and withdrawal to be made by means of a pair of tongs. It should also be so built in

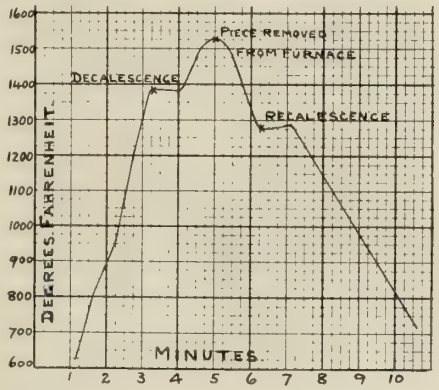

Diagram showing "Decalescence" and "Recalescence" Periods

the fire that all parts of it can be evenly heated by using a steady blast.

Great care must be taken that an even temperature be given those parts of the tool that require to be hardened, and it is advisable to continue the heat even for a short time after the "decalescence" point has been reached, for two reasons. In the first place, it insures the chemical change taking place, not merely on the surface, but through to the centre of the piece; and, secondly, it allows for the loss of heat by radiation, which takes place when the piece is removed to the quenching bath.

Cooling or Quenching.

Cooling or quenching, which sets or fixes the "cementite" in "solid solution" with the "ferrite," and completes the hardening process, requires as great care as heating, and here, again, temperature is a governing factor. There are three cooling mediums in general use—water, brine and oil, but for carbon steel tools, water is undoubtedly the safest and cheapest. Careful experiments have shown that rain water at a temperature of 45 to 50 degrees Fah., gives the best results. Temperatures below 45 degrees have a tendency to cause the steel to crack and warp. Again, should the bath be too warm, the hardest results are not obtainable. When dipping, care should be taken that the tool enters the bath vertically and point or edge downwards. It should not be held stationary in the bath, but moved gently from side to side, in order that cold water may constantly come in contact with its heated sides, thus insuring a quick, uniform reduction of temperature.

The tool should be allowed to remain in the quenching bath until it has been reduced to the same temperature as the bath itself, and when withdrawn, if the methods explained have been carefully followed, it will be found to have attained the greatest degree of hardness possible to impart to that particular steel, without altering its shape or dimensions and without cracking and flakeing.

C. P. R. SHOPS, CALGARY, ALTA.

Concerning the new C.P.R. shops at Calgary, Alta., it is of course known that these will occupy an area of 120 acres of good land, and will employ about 5,000 men. Other than that the shops will resemble those of the company at Montreal, no official statement has as yet been made. It is probable, however, that there will be at least twenty buildings, including freight car, passenger car, and locomotive repairing shops. The locomotive shop, will alone, it is said, cover six acres of land. The machinery to be installed will be of the very latest design and the tool equipment will be likewise very complete.

The shops at Calgary are intended to provide for repairs to equipment on the company's western lines. At one time, the Angus shops at Montreal and the shops at Winnipeg were sufficient for this work but the equipment has increased to such an extent within the last few years, that the Calgary shops have become a necessity. The following table shows the additions made to the C.P.R.'s equipment since 1886.

	1886	1911
Locomotives	372	1,639
First and second class passenger cars, colonist and baggage cars	304	1,757
First class sleeping and dining cars	47	211
Parlor official and paymaster's cars	27	63
Freight cars and cattle cars ... ..., ...	8,253	50,863

Mechanical Drawing and Sketching for Machinists*

By B. P.

A Series of Progressive Lessons Designed to Familiarize Mechanics With the Use of the Apparatus Necessary to Make Simple Drawings, to Encourage them to Realize How Important a Factor it is of Their Equipment, as Well as Being a Profitable Pastime.

THE Christmas and New Year holidays being over, the work of self-improvement should be resumed with new vigor and enthusiasm. Too often the festive season sees the end of a once firm resolve to pursue a predetermined course of study right through the winter, and a more than ordinary effort is required to combat the recreative tendency. By carefully selected examples and exercises, the writer hopes to maintain the interest of his readers until the end of the course, and will spare no pains to attain his objective.

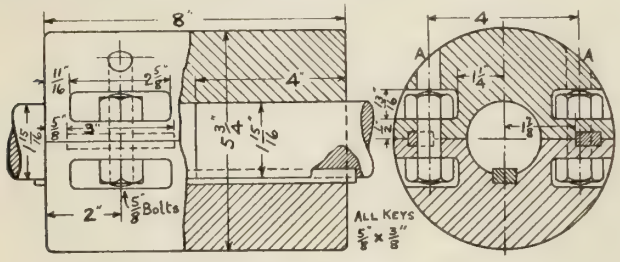

Fig. 1—Drawing and Sketching.

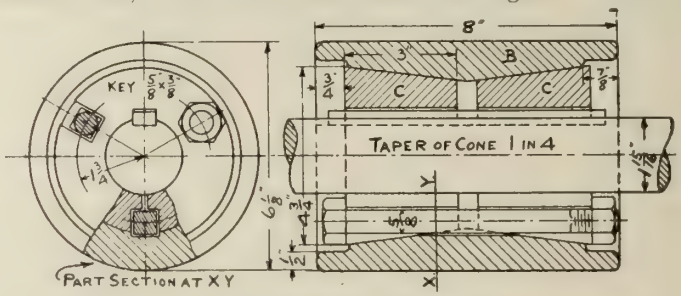

Fig. 2—Drawing and Sketching.

Shaft Couplings.

Fig. 1 shows one method of coupling two ends of a line shaft. This is known as a split muff coupling, and consists of two similar iron castings jointed along the centre line of the shaft. By means of the four bolts with nuts at each end, the shaft is tightly gripped. For shafting larger than 3 inches diameter, six bolts are generally used. Recesses for the nuts, cast in the coupling, are made wide enough to allow of their being tightened with a spanner. The four keys on the line of the joint take the shear off the bolts, while the long key at the bottom of the shaft prevents all possibility of slipping. All the keys fit on the sides only and have no taper. The bolt holes are drilled from the circumference as shown at A. Draw to half size and add a plan view.

Sellers' Compression Coupling.

This coupling is shown in Fig. 2, and consists of a cast-iron muff B, bored out to a double conical form, and two split cast-iron conical sleeves C.C., which are pulled together by bolts as shown. The taper of these sleeves is 3 inches on the diameter per foot of length. As the bolts are tightened up, the friction between the sleeves and the shaft becomes greater, and may be quite sufficient to prevent slipping; but as additional security, a side-fitting sunk key without taper may be added. The bodies of the bolts are made square to prevent turning when the nuts are being tightened up, or the bodies may be round and the bolt heads made square and recessed into the end of the conical sleeve against which they bear, thus effecting the same purpose. This form of coupling is frequently met with, the outside being slightly crowned so that it may serve as a belt pulley if required. Most of the dimensions necessary have been given and the student should use his judgment in supplying any omissions.

Cast Iron Belt Pulley.

Fig. 3 shows a cast iron belt pulley with six curved arms. These are less liable to crack through contraction strains when cooling in the mold than are straight arms, but the latter are better in other respects, being both stronger and lighter. It is unusual to find curved arms in a pulley so small as that shown in Fig. 3, but they are there introduced in order to provide a useful exercise. Two complete arms are shown, as well as the centre lines of the other four, and the student should have no difficulty in finishing the drawing to a scale of one-fourth full size.

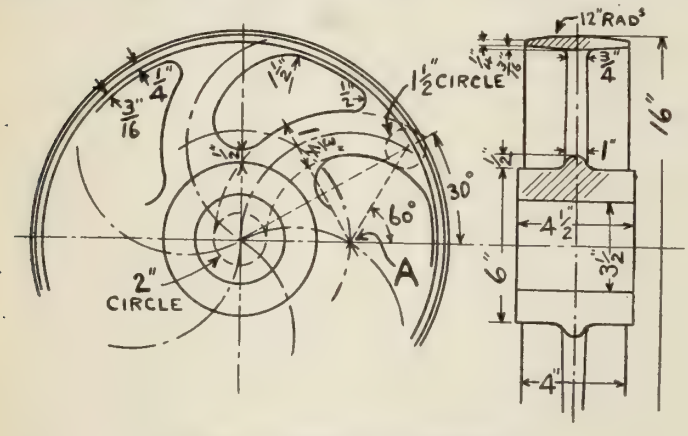

Fig. 3.—Drawing and Sketching.

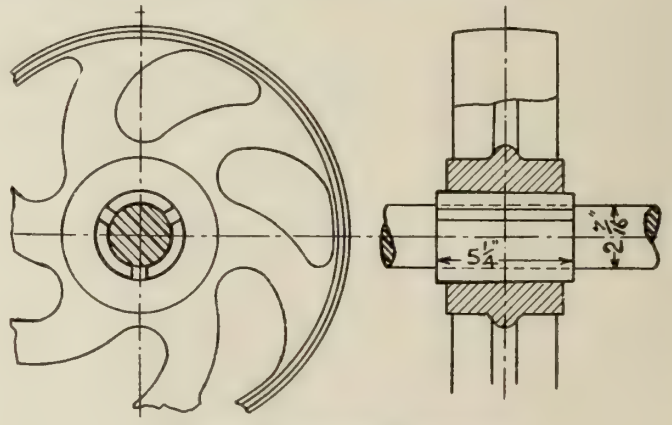

Fig. 4.—Drawing and sketching.

Having laid down the centre lines, draw a circle to represent the 16 inches outside diameter of the pulley. From the centre, draw a line at 30 degrees with the horizontal, as shown. On this line draw a circle 1½ inches diameter, having its centre ¾ inch from the outside of the pulley. From the centre of this circle

*Eleventh of a series of an Instruction Course.

draw a line at 60 degrees with the horizontal. The point A, where this line cuts the horizontal centre line of the pulley, is the centre from which the centre line of the first arm is struck, the radius of course being the distance from A to the centre of the pulley, or, what is the same thing—to the centre of the 1½ inch circle.

From the centre of the pulley draw a dotted circle through the point A; part only of this being shown in the figure. Divide the circumference of this circle into six equal parts by meaos of the 60 degree set square. Each of the points thus obtained will be the centre from which an arm is struck.

The arms are seen to be tapered slightly in the elevation, being 1½ inches at the rim, and increasing uniformly so as to be 2 inches wide at the centre were they extended thus far. From this it is clear, that half way between these two points the mean width will be 1¾ ins. From A draw a straight line at right angles to the 30 degree line and continue till it cuts the curved centre line of the arm. Mark off 1¾ inches width here, and through these marks draw radii to touch the 1½ and 2 inch circles. Both will have their centres very near the point A; the larger radius being centred a little to the left, and the smaller a little to the right.

The sectional view shows that the rim of the pulley is crowned to a radius of 12 inches, and that the thickness of the arms is ¾ inch at the rim and 1 inch at the hub. The section shown being a conventional one. It gives all the required information, however, and is the usual method employed when showing such objects. A true section, would, of course, show part of the arm in section, as well as the rim and hub.

The hole in the hub is larger than the shaft, to allow it to be passed over projecting collars or bosses on the latter. The cone keys shown in Fig. 4, constitute the fastening. These are of cast iron, in one piece, but nearly cut through by parting plates inserted in the mold. After boring out and being turned taper on the outside, they are then cut completely through, and form three segmental tapering keys which fill up the space between the hub and shaft.

Exercises.

1.—Draw separately each part of the coupling shown in figure 2, together with all necessary views and dimensions.

2.—Draw a cast iron pulley similar to that shown in Fig. 3. Pulley to be 30 inches diameter, with 8 arms, and keyed to a 3 7-16-inch shaft by sunk key 1 inch wide and ½ inch thick, instead of by method shown in Fig. 4.

THE "MILLEN-IUM" CONVENTION

Business acumen is to our mind the most applicable expression with which to characterize the recent convention of the staff of John Millen & Sons, and the leading representative men whose various manufactures are embraced under the trade mark "Millen-ium". This conference, the second annual function of its kind, demonstrates unmistakably the benefits derivable from a staff, which, while not only loyal, is in addition, intelligently so. Short talks were given at the business sessions

covering the many trade specialties handled by the firm. These gave salesmen an opportunity of becoming familiar with their product in its every feature, and the wise interspersal of a "question box" and social hour rendered available, later, supplemental and more minutely detailed explanation.

The convention lasted three full days, and its layout gives ample suggestion that "Millen-ium" development and progress for the New Year, 1912, is well on the way to be fulfilled. The headquarters of John Millen & Sons are at Montreal, while branches are established in Toronto, Winnipeg and Vancouver.

COLLIERY OVERWINDING.

The question of the prevention of overwinding at collieries has been brought prominently to the front of late, and at several of the South Yorkshire pits, ap-

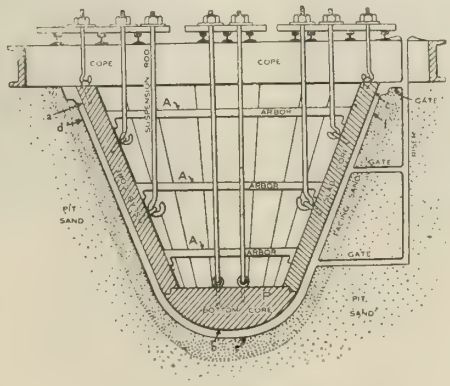

Fig. 5.—Section Through Mold.

pliances for the purpose are already operating. The members of the Midland Institute of Mining, Civil, and Mechanical Engineers, inspected one of these recently, at the invitation of the South Kirby, Featherstone, and Hemsworth Collieries. The Shaw Overwinder, which is installed at these pits, is the invention of the late John Shaw, chairman of the company. It is at work in the winding-house belonging to the Haigh Moor pit, and the visitors saw it tested under ordinary working conditions. It is also being erected in the engine-house for the Barnsley pit.

The gear consists of two nuts travelling in the same direction on a horizontal screw, and each representing one of the cages. It is designed both to reduce the speed of winding and to stop the engine in case the engineman should fail to do either at the proper moment. If he does not reduce speed, the depression of a lever releases a weighted bar, which falls, closing the throttle-valve, cutting of the steam or other motive power, applying the brake, and thus automatically pulling up the engine. A final brake prevents overwinding. Should the gear come into action it can be reset and winding operations resumed within two minutes.

LEGAL NOTES.

Frank D. Simpson, laborer, Hamilton, Ont., by virtue of a decision in the Divisional Court at Osgoode Hall, Toronto, will receive $400 damages for the crushing of his thumb and fingers in a "tumbler" machine at the works of the Tallman Brass & Metal Co. Simpson alleged that the machinery was defective by reason of the fact that there was no mechanical belt shifter for the belt which operated the machine. Mr. Justice Britton says he finds it hard to believe the plaintiff's story, that he had tried to start the machine with a crowbar and by other means, but had failed, and it was when he had slipped the belt to the loose pulley that it suddenly slipped back to the fast pulley and started the machine, which caught and crushed his hand. This, the judge remarked, was a matter of fact for the jury, which accepted the story.

MOLDING LARGE SLAG LADLES.

THE Prime Steel Co., Milwaukee, have cast what are believed to be the largest slag ladles ever manufactured. Each ladle is a solid steel casting, and in its production some rather difficult problems in molding and coremaking were successfully solved. The ladle weighs 20,000 pounds and is 10 feet 5 inches diameter across the top, and 8 feet 6 inches deep inside. The capacity is 300 cubic feet. With the exception of the rim, the metal at the top is 1¼ inches thick, increasing to 2¾ inches at the bottom, which is bowl-shaped.

The mold is made in a pit, the ladle being cast right side up. The conical core, which forms the inside of the mold, is suspended from the cope. Fig. 5

shows a cross-section of the mold with the core in place. Fig. 1 shows the cope with the suspended core beneath. In making the mold, the sand is first swept out, forming a cavity exactly the size of the inside of the ladle, and re-

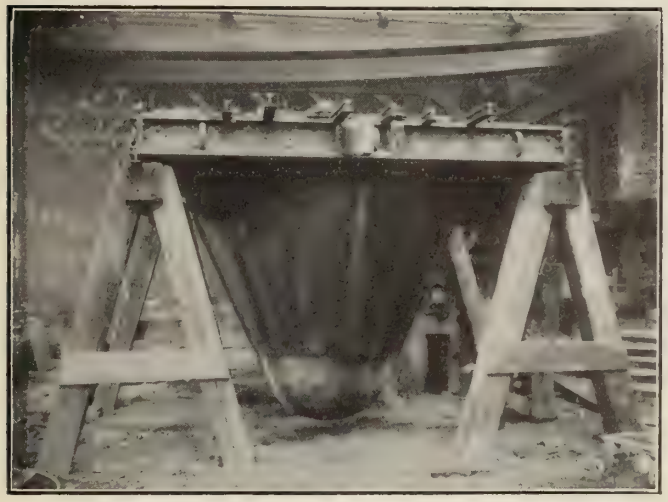

Fig. 1.—Cope with Core Assembled, Before Placing in Mould.

Fig. 2.—Conical Core Slab Suspended.

presented by the line, abc, fig. 5. The core is then assembled in this cavity and the cope finished. The cope with the core is next withdrawn, and the mold swept out again, this time to a size corresponding with the outside of the ladle, as indicated by the line def,

Fig. 3—Ladles after Shaking-out, showing Pouring Gates and Risers.

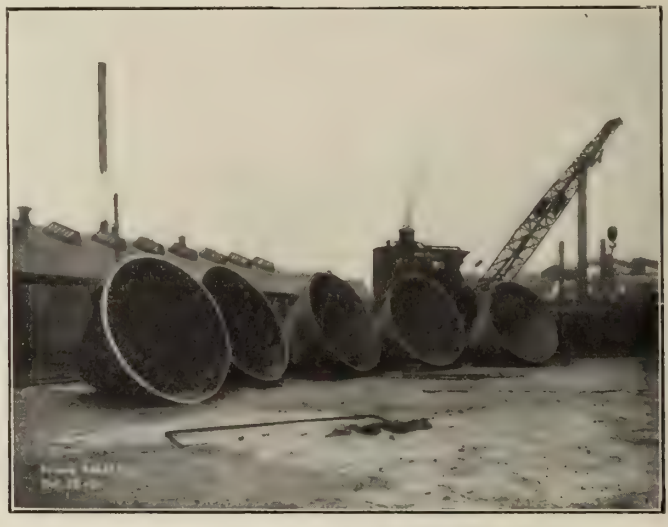

Fig. 4.—Ladles Awaiting Shipment.

fig. 5. The cope and core are afterwards replaced, and the mold finished.

The Core.

The core is one of the most interesting features of the mold. It is built-up, and consists of 16 separate pieces. Its general construction is indicated in figs. 1 and 5. Referring to these illustrations, it will be noted that it consists of a solid, bowl-shaped bottom piece P, fig. 5, made exactly the shape of the ladle bottom, with 15 wedge-shaped slab cores resting on the bottom piece and forming the conical, inside surface of the mold. The whole core is suspended by rods from the cope. Four $1\frac{1}{4}$-inch rods carry the bottom core, and each slab core is also provided with three suspension rods, two on the side and one on the top, as indicated in fig. 5.

The slabs, indicated by the cross, fig. 2, are each seven inches thick and 6 feet 3 inches wide at the bottom. They are very strongly made, being heavily reinforced with steel rods and provided with suitable eyes to receive the suspension rods. The bottom piece is also strongly reinforced. Several cast steel arbors, A, fig. 5, are inserted in the hollow conical part of the core to resist crushing stresses.

The cope flask, about 15 feet square and 18 inches high, is made of cast steel with steel cross-bars, and from it this core is suspended. Its sides are similar in cross-section to a rolled channel. Steel rails are laid across the top of the cope, and the washers under the suspension rod nuts rest on these rails, thus distributing the weight of the core. The cope and core together weigh about 20 tons. Great care is taken that the core shall be stiff and able to resist considerable crushing stress and also the upward pressure of the fluid metal in the mold.

The inside of the mold is skin-dried before the cope is replaced. Only one pouring gate is used, as shown in fig. 3. It consists of a riser, about three inches diameter, extending vertically into the sand and provided with three feeding gates, one at the top, one about one-third and one about two-thirds of the distance down the side of the ladle. The gates are about 2x4 inches in cross-section. Six small sink heads are spaced equi-distant around the top of the ladle. The mold was made in the manner described in order to be certain that there would be no cracks or checks in the finished product.

Casting the Ladle.

The metal is poured from a 20-ton

ladle, and is run into the mold as hot as possible. Ordinary steel is used melted in an acid, oil-burning open-hearth furnace. After the casting has cooled, it is taken out of the mold by the crane, shown in fig. 3. The gates and heads are cut off and the interior and exterior of the ladle smoothed-up with a portable emery grinder.

We are indebted to the Prime Steel Co. for the illustrations, and to the Iron Trade Journal for the descriptive text.

CANADIAN METAL PRODUCTS CO.

It is understood that Mr. N. Curry, president of the Canadian Car & Foundry Co., will be asked to take the presidency of the new Canadian Metal Products Co. which will be established as a result of the visit which several Montreal gentlemen made to College Point, about twelve miles from the city of New York. They there inspected the plant of the United States Metal Products Co., which has a capital of $8,000,000, and 2,000 men on the payroll. Mr. F. W. Fairman promoted the excursion, which was composed of R. Curry, W. F. Angus, Milton Hersey, J. W. McConnell, Lorne Webster, F. H. Hopkins and Arthur M. Irvine. They returned to Montreal not only satisfied with what they saw at College Point, but decided to establish a plant in Montreal. The new company hope to be in full working order in three months' time.

It is understood that there will be an issue of accumulative seven per cent. preferred stock by the Canadian company, amounting to $500,000, together with $1,000,000 of common, and the statement was made to-day that the preferred stock will be taken by the United States Metal Products Co., which will have a representative on the board.

The machinery to be installed will cost about $150,000, and employment will be given to a large number of skilled hands. The company will manufacture all kinds of metal window frames, doors, etc.; in fact everything connected with the interior fittings of buildings, both large and small.

LOCOMOTIVE CONVEYING PLANT.

The erecting shop of the Cockerill locomotive works is connected to the station of Seraing by a branch line having curves with a radius of only 50 metres. This is insufficient to permit the passage of the heavy locomotives, types 10 and 36, lately put in service by the Belgian State Railways, as they are unable to round curves of less than 150 metres radius. The erection of an interesting appliance to convey these engines from the works to the station and vice versa, has, therefore, became necessary.

The apparatus consists of two electrically driven elevators of 150 tons lifting power, located one in the works and one at the station of Seraing, and capable of moving a platform bogie wagon on which the locomotive is loaded. The elevators are installed in concrete pits, and their control comprises the operations of placing the empty wagon on the platform, lowering the elevator below the track level, fixing the locomotive on the wagon, lifting the elevator and hauling the loaded wagon to the station, where the inverse operations are performed for placing the locomotive on the railroad tracks. Each of the elevators is fitted with a series wound motor developing 35 h.p., which actuates, by means of a bevel gear system, a transverse shaft driving two longitudinal shafts. These, in turn, by means of mitre-wheels and large nuts in phosphor bronze, give a vertical motion to eight right and left handed screw spindles in forged steel of 112mm. outside diameter. Each of these spindles is capable of sustaining a load of 20 tons, and rests on a thrust-bearing in ferro-concrete. The eight change-speed gears are enclosed in grease boxes fitted with stuffing boxes of special design. The mechanical part weighs about 13,500kg., and was supplied by Messrs. Beer, of Jemeppe-sur-Meuse.

The frame work, weighing about 15,500kg., and constructed by the Ateliers Metaliurgiques of La Sambre, near Charleroi, consists of two plate girders composed each of a web 720 by 12mm., four flange plates 280 by 10mm., and four boom angles 120 by 120 by 12mm., with a height of 765mm. These main girders are supported by four cross girders of the double web box type made of mild steel plates and angles, to which a vertical motion is imparted by means of the eight screw spindles. The elevators are designed for a load of 150 tons, of which 120 tons is accounted for by the load conveyed and 30 tons by the tare-weight of the wagon.

The wagon is carried on bogies each composed of four axles fitted with wheels of 700mm. diameter on the tread; the weight supported by each wheel being 9,375kg. The wheelbase is 11,200 metres, and has been calculated so as to allow the wagon to pass freely over curves of 50 metres radius. The total length of the underframe is 16 metres, the outside breadth over headstocks 2.640 metres, the width of the underframe 1.925 metres, and the height above rail 1.460 metres. The platform is fitted with rails on which the locomotive is pushed; their ends when it is lowered in the pits, fitting exactly those of the tracks. Powerful clamps are provided for securing the locomotive, the wagon being obliged to run over a line having a gradient of 25mm. per metre.—T.E.S.

COMPENSATION FOR INJURIES.

Compensation for injuries received in an accident at the Edmonton Iron Works in June of this year, was sought in the district court recently, through an action brought against the company by John Petratus, who sustained a broken ankle, while at work in the plant. The proceedings were instituted under the common law, the plaintiff also presenting his claim under the workmen's compensation act, in case the common law suits should fail. Under the first head, Petratus seeks to recover an amount totalling in round figures $400. If the judge should decide that the claim under the common law is invalid, the plaintiff will be able to recover a much smaller amount, probably less than $100, under the compensation law.

Petratus was assisting in the drilling of bolt holes in a steel girder when the accident occurred. Two other men were working in the vicinity and as they lifted a girder from its place, the mass of wrought steel swung around, knocking Petratus from the trestle on which he stood. A heavy I beam fell across his foot, breaking a small bone and incapacitating him for work for some six weeks. He was in the hospital for a couple of weeks, and for a month after his discharge he was unable to work. Finally, he secured a job with the city. His wages were garnisheed by his doctor to the amount of $62.50.

Judge Taylor reserved his decision in the case.

SUPERHEATED STEAM FOR LOCOMOTIVES.

All the Scottish railway companies have now experimented with superheated steam on locomotives, and have decided that the system is a great improvement. The Caledonian Railway began about two years ago, when they fitted the Schmidt apparatus on a four-coupled passenger express engine. The trials were satisfactory, and four additional engines of the same type were similarly fitted. Now the company are running seven engines with superheated steam, two are being fitted, and four new engines are to be equipped with the apparatus. They have found that the working pressure can be reduced from 180 lbs. and 200 lb. to 160 lb. and 165 lb. In the earlier engines fitted, the cylinders have been increased from 19 in. to 20 in. diameter, while in the later locomotives, the diameter is 21 in.

The North British Railway Co. are

equipping four of their express locomotives with superheating apparatus. Two have been running for some time with the Phoenix or "smokebox" type, and two new 4-4-0 engines, of the "Walter Scott" class will have the Schmidt type. Recently the Highland Railway Co. have built a locomotive fitted with the Phoenix superheater, but it has not yet been in service. The Great North of Scotland Co. are also making arrangements for giving superheated steam a trial.

It is interesting to note, in this connection, that the Scottish companies are restricting the use of superheated steam, for the present at least, to main line locomotives, as they believe that the best results are obtained on long-distance runs.

CITY OF SOREL, P. Q.

The City of Sorel, Que., 50 miles from Montreal on the south shore of the St. Lawrence, is undergoing considerable expansion and development. In addition, steps are being taken to locate manufacturing plants there, and with this end in view, the City Council is offering exceptional privileges. The water transportation facilities are probably unequalled in Eastern Canada, the city not only being on the direct routes to Europe via the River St. Lawrence, and to the Great Lakes via Lake Champlain, but possessing as well a harbor capable of accommodating ocean-going vessels. There is abundance of cheap labor and electric power, and the council, having retained several good factory sites, are prepared to grant liberal concession. It is confidently expected that as a result of the present movement, Sorel will become one of the leading manufacturing centres in the Province of Quebec.

COST OF PUBLIC WORKS.

Expenditures on Public Works in Canada last year totalled $11,807,055, according to the annual report just issued by the department. How the figures of outlay have grown is indicated in an interesting corporation table. Twenty years ago the total was $2,711,420. Ten years later it was $4,699,680, and last year it reached five times that of 1891. The expenditure for the twelve months was divided as follows; Harbors and rivers, $2,975,059; dredging plants, $4,471,203; slides and booms, $190,187; roads and bridges, $90,061; public buildings, $3,090,665 ; telegraphs, $568,493 ; miscellaneous, $421,364

The report gives a detailed description of harbor improvements in different parts of the country, and also characterizes as feasible the proposed Saskatchewan river waterway. With the expenditure of a million and a half dollars it is believed that the river can be made navigable for small craft and barges between La Pas and Prince Albert.

MAY USE OLD STYLE ENGINES.

There is said to be a strong possibility that the Pennsylvania will go back to the old style of passenger locomotive if experiments that are being made continue to give satisfactory results. For some time, the company has been compiling statistics relative to fuel consumption on passenger engines. It is stated that certain of these show a saving in the operation of particular trains, while others do better with heavier hauls. The new engines in use for several years have made good in the matter of speed, but as only some trains require that extra speed be made, the officials believe that those making more stops and operated on a slower schedule can get along very well with the old style engine.

ENGINEERS' CLUB, MONTREAL.

Mr. J. W. Fraser read a paper, illustrated by slides, at the Engineers' Club, Montreal, on the Southern Power Company's Transmission Lines, which operate in Northern Carolina. In tracing the early stages of electrical transmission, the lecturer mentioned that the Missouri River Power Plant was the first to operate commercially at 50,000 volts, and the Shawinigan transmission to Montreal was put into service a few months later. The Southern Power Company had been organized in 1905 for the purpose of developing certain water powers on the Catawba and Broad rivers. It had been built in sections, and in 1909 a 100,000 volt line of 250 miles was put in service. Since that time, a second circuit had been added and 140 additional miles of two-circuit 100,000 volt lines completed ; a total of 1,380 miles of three-phase line. The greater part of the power was used by cotton mills. At the conclusion of the paper, which the chairman described as one of the most valuable contributions to the electrical section of the club, a short discussion ensued, and thanks were expressed to the lecturer, who, it was pointed out, was an old McGill man.

NEW SCHOLARSHIP IN ENGINEERING.

Through the generosity of the Boiler Inspection and Insurance Co. of Canada, the department of Mechanical Engineering of the University of Toronto has been made the recipient of a scholarship of the value of the fees of the fourth year. The award is to be made to the student who stands first in honors in the work of the third year in that department. It is to be hoped that the action of the Boiler Inspection and Insurance Co. in this matter may encourage others to take a like interest in the work of the institution. What is here done for mechanical engineering can be done for other departments, and by this means, the bonds between the applied sciences and the industries will be greatly strengthened.

IRON AND STEEL OUTLOOK.

With the beginning of 1912, fully 100,000 idle workmen will find employment in the iron and steel industries of the United States. Every plant in operation will largely increase its complement of workmen, and scores of mills and furnaces that have been idle will resume output. During January, there will be 237 blast furnaces in operation, as against 211 at the beginning of December. Reports from eastern, western and southern iron and steel concerns, all indicate increased activity with the beginning of the year.

Personal

Leo G. Smith has resigned his position as general superintendent of the steel foundry department of the Londonderry Iron and Mining Co., Londonderry, Nova Scotia.

Mr. R. B. Coulson, for a number of years selling agent for the Dominion Wire Mfg. Co., has left for Sydney to join the staff of the Dominion Steel Co. After a short stay at Sydney, Mr. Coulson will return to Montreal making his headquarters there. His time will be devoted to the wire products department of the company.

F. A. Yerbury, vice-pres., the Canadian Boving Co., Bay St., Toronto severed his connection with that firm on 31st December. He has accepted an appointment with the Heaps Engineering Co., Ltd., Vancouver, a particularly strong concern who have in project the establishment of large rolling mills, an electric steel making furnace, also a shipbuilding plant, and will manufacture in addition to the products of the foregoing, internal combustion motors for automobile and marine requirements. Mr. Yerbury's name will always be associated with the successful introduction of the Diesel Oil Engine into Canada, and the fact that he has a large personal interest in the Heaps Engineering Co., is sufficient augury of his and its future.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

FOUNDRY AND MACHINE SHOPS.

Bridgeburg, Ont.—Tuttle & Bailey Mfg. Co. will erect a large foundry here in the south ward.

Welland, Ont.—The Electro Steel Plant, which has been in the hands of the receiver for some time, has been purchased by C. J. Laughlin and A. M. Mosley. It is stated that a factory for the manufacture of bolts and nuts will be started shortly.

Winnipeg, Man.—The Winnipeg Tool & Forging Co. (Geo. F. Fowle and Henry F. Waters) has been dissolved.

Sherbrooke, Que.—The city will make a loan of $100,000 without interest for ten years to the Jenckes Machine Co., for the purpose of doubling the plant.

Kindersley, Sask.—Messrs. W. J. Hay, S. Pine, C. A. Nugent and G. A. Lucas are opening an up-to-date machine shop and garage here.

Hamilton, Ont.—Big additions will be made to the plant of the Steel Company of Canada here. This includes two fifty-ton open hearth furnaces, a 32-inch high blooming mill, a continuing mill and a combination rod and bar mill.

Newmarket, Ont.—The ratepayers have passed the by-law to loan the Harding Auto Co., of London, Ont., $25,000, to aid the establishment of a plant here.

Wingham, Ont.—The by-law to grant a loan to the Western Foundry Co. was carried by the ratepayers.

Brampton, Ont.—The burgesses passed a by-law to loan $43,000 to the Pease Foundry Co., to assist them in locating here.

Farnham, Que.—The Pickering Patent Wheel Co. have secured a factory and site, and will locate their plant here.

Ottawa, Ont.—The Ottawa Iron & Steel Co. have been incorporated and are planning to expend $150,000 here on a plant. Structural steel will be manufactured, and it is expected that the blast furnaces will be in running order by next summer.

Edmonton, Alta.—The Edmonton Iron Works have secured a new site in Riverview, and will move their plant there next summer. It will be enlarged to four times its present size and new departments will be added for the manufacture of new lines of machinery.

Weyburn, Sask.—J. A. Shetlah and Jas. Gilmore are opening a new implement firm here to take the place of the defunct Weyburn Implement Co. Besides a line of implements and machinery, they will hold the agency for several makes of automobiles.

Winnipeg, Man.—The school board has purchased machinery to the value of $60,796.96 for the machine, forge, foundry and pattern-making rooms of the Kelvin and St. John's Technical High Schools.

Montreal, Que.—A small fire damaged the roof of the power house at the Steel Company of Canada recently.

Brandon, Man.—A large southern automobile manufacturing concern is in touch with the publicity bureau with a view to locating here. Firms from Ohio and Indianapolis are also in communication.

Weyburn, Sask.—A small fire caused slight damage to the Beischel machine warehouse here recently.

Midland, Ont.—The Standard Iron & Chemical Co., of Toronto, are negotiating with the town with a view to locating an iron furnace here.

Port Arthur, Ont.—The city has signed an agreement with a firm to be known as the Steel Products Co., which now has a plant at Morrisburg, but will move it here and engage in the manufacture of sheet metal.

Port Colborne, Ont.—The Buffalo Union Furnace Co. is making arrangements to establish here.

Niagara Falls, Ont.—The M. E. Blasier Machine Co., Utica, N. Y., will establish a plant here and manufacture tailors' machines.

Sherbrooke, Que.—An iron foundry company are negotiating with the city, and will probably establish a plant here.

Calgary, Alta.—The contract for the C. P. R. shops has been sent to the Westinghouse-Church-Kerr Co., N. Y., by Vice-President Bury. They will be the same size as the Winnipeg shops, and if built according to the schedule will be completed by the end of this year.

St. Thomas, Ont.—The annual meeting of the shareholders of the C. Norsworthy Co. was held here recently, and on account of the excellent showing it was decided to extend the Howard Furnace business. About $10,000 will be expended on this.

Toronto, Ont.—The Schacht Motor Car Co. will erect a $25,000 garage on Richmond Street West here.

Ridgetown, Ont.—The R. Watt Machine Co., manufacturers of separators, self-feeders, bean threshers and windmills, are erecting large additions to their present shops.

St. John, N. B.—The St. John Railway Co. will hereafter build its own cars, thus adding to the list of important industrial concerns established here.

Vancouver, B. C.—The E. A. Heaps Co. are preparing to build a big machine plant near their lumber mills. They will conduct a general machine shop and engineering business.

Grand Forks, B. C.—The Granby Smelter has resumed operations, six of the eight furnaces being in operation. They were compelled to shut down because of the loss of their coke supply, occasioned by the recent coal strike. The British Columbia Copper Co. are also reopening their plant.

Brantford, Ont.—The Brantford Oven & Rack Co. will build a new factory here.

Hamilton, Ont.—The council has passed a by-law granting certain concessions to the Steel Company of Canada, which contemplates making extensive additions.

Vancouver, B. C.—G. M. Gibbs, Granville Street, is directing a company that will equip a large new steel mill on the Fraser River, near here.

Port Arthur, Ont.—W. J. Lindsay is promoting a company which contemplates establishing here. They will manufacture stoves and heating applances. A $200,000 plant will be erected.

Kingston, Ont.—The ratepayers are being asked to grant a fixed assessment of $100,000 to the locomotive works.

Napanee, Ont.—The Dominion Rock Drill & Foundry Co. are asking for a fixed assessment from the town.

Owen Sound, Ont.—H. Cole proposes to establish a bolt and nut foundry here, and he is asking for a loan of $20,000.

Kamloops, B. C.—Fire did about $3,000 damage to the machine shop of J. W. Ellis & Co. here recently.

Orillia, Ont.—The ratepayers are being asked to grant certain concessions to the National Hardware Co.

MUNICIPAL.

London, Ont.—It is proposed to expend $50,000 for an incinerator and plant.

Exeter, Ont.—The ratepayers are being asked to sanction an expenditure of $5,000 to extend the waterworks.

Dunnville, Ont.—If the ratepayers give their assent, $9,400 will be spent in improving the sewerage system.

Carleton Place, Ont. It is proposed to expend $150,000 for a waterworks system.

Edmonds, Burnaby, B. C.—The ratepayers are asked to vote $250,000 for waterworks.

Ottawa, Ont.—Plans have been prepared for improvements to the waterworks entailing an expenditure of $2,300,000.

Barrie, Ont.—The burgesses are being asked to provide $21,100 for sewerage purposes.

Hamilton, Ont.—It is proposed to erect a public convenience here to cost about $18,500.

Stratford, Ont.—The city will expend $23,000 extending and improving the waterworks system.

Saskatoon, Sask.—By-laws totalling $514,000 for various civic enterprises were passed by the ratepayers.

North Battleford, Sask.—The municipality will expend a considerable sum extending the waterworks system.

Scott, Sask.—The ratepayers passed four by-laws for sidewalks, water, light and sewers.

ELECTRICAL.

Waterdown, Ont.—The by-law to provide $5,000 to instal a Hydro-Electric power plant has been passed by the ratepayers.

Kamloops, B. C.—It is proposed to spend $300,000 for a Hydro-Electric project at Barrier River.

North Battleford, Sask.—The ratepayers passed the by-law to expend $94,000 on electric light extensions.

Brampton, Ont.—It has been left to the ratepayers to decide whether or not the town will purchase the electric light and power interests of John McMurchy, for the sum of $15,000.

Paris, Ont.—It is proposed to expend $25,000 to instal Hydro-Electric power here.

Petrolea, Ont.—$6,000 will be spent to complete the Hydro-Electric system.

Port Credit, Ont.—The ratepayers are being asked to sanction an expenditure of $7,500 to complete the Hydro-Electric power plant.

Tillsonburg, Ont.—The ratepayers are being asked to provide $6,000 to complete the Hydro-Electric system.

Forest, Ont.—It is proposed to expend $20,000 on an electric light plant.

Toronto, Ont.—Toronto has plans calling for an expenditure of $2,200,000 to complete the Hydro-Electric system.

Richmond Hill, Ont.—Steps are being taken to provide $5,000 for electric lighting purposes.

Renfrew, Ont.—It is proposed to expend $60,000 for power extensions, etc.

Woodstock, Ont.—The ratepayers are being asked to provide $10,000 for lighting purposes.

Ottawa, Ont.—The E. B. Eddy Co., of Hull, have planned improvements which will cost upwards of half a million dollars. The projects include the electrification of the whole factory of the company by means of a 1,200 h.p. plant. Water power will be done away with. It will take about two years to complete the improvements.

BUILDING NOTES.

Moose Jaw, Sask.—The Robin Hood Mills, which were wiped out a short time ago by a disastrous fire, will be rebuilt on a larger scale than ever.

Vancouver, B. C.—The London and British North America Co. will erect a $250,000 nine-storey building here at once. Somerville & Putnam are the architects.

Montreal, Que.—Johnson Bros., jewelers, will next May erect a five-storey building to cost $150,000. It will be of steel and concrete.

Toronto, Ont.—Messrs. H. H. Macnamara and H. Gagnier have been granted a permit for a $100,000 office building at the corner of Richmond and Sheppard streets.

Winnipeg, Man.—Messrs. Burke, Horgood & White, architects, of Toronto, are preparing plans for a $2,000,000 departmental store to be erected here for the Hudson's Bay Co.

PLANING MILL AND SAW MILL.

Red Deer, Alta.—Cushing Bros., owing to their growing business at this point, propose building a new sash and door factory here next spring. Seven or eight machines will be installed.

South Vancouver, B. C.—The building inspector has issued a permit to the Coast Lumber & Fuel Co. for the erection of a lumber mill; and also one to the South Vancouver Lumber Co. for a mill at Fraser River, the latter to cost about $12,000.

Victoria, B. C.—The Canadian Puget Sound Lumber Co. are about to make a large addition to their mill plant here. They will erect a three-storey building at a cost of $40,000. Other improvements are now under way.

Toronto, Ont.—Fire did $45,000 damage to the planing mill of the William A. Dunn Lumber Co. here.

South Vancouver, B. C.—Robert Nesbitt, a Vancouver real estate broker, is promoting a company that proposes to establish lumber yards here. $25,000 will be invested.

St. Marys, N. B.—Wm. H. Gunter has purchased the Babbitt estate mill here. The new owner will assume active management next season.

Red Deer, Alta.—E. Rivard, of Calgary, has secured a site in North Red Deer, where he and two partners will build a sash and door factory.

Port Hammond, B. C.—The mill of the Bailey Lumber Co. is about to commence operations once more. New machinery is being installed and several extensions will be made to the plant.

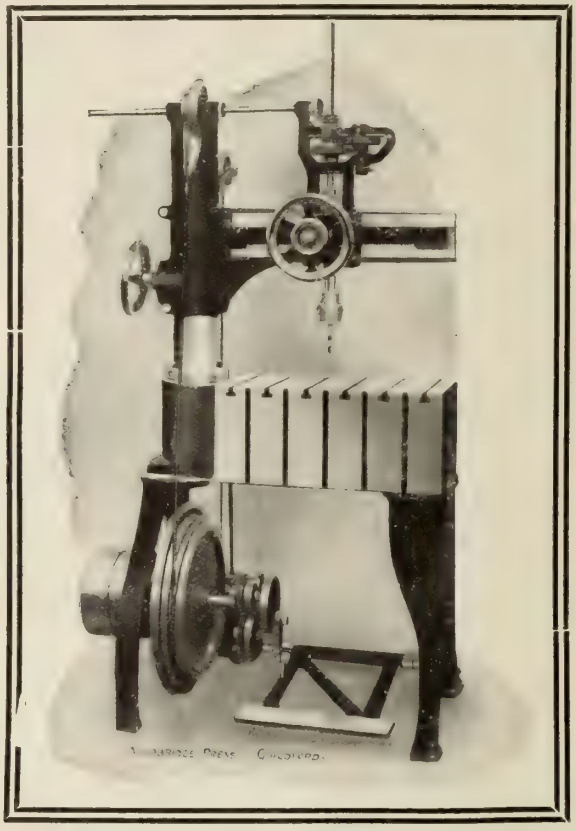
GENERAL MANUFACTURING.

Midland, Ont.—There is a proposition on foot here to grant a fixed assessment to J. A. Benson and M. J. Bray, to assist in the establishment of a woodworking plant here.

A Radial Drill

that will by foot power drill holes up to one inch without a pilot hole, at the speed of an inch in six minutes; with the slotted wings for awkward work; inexpensive, but one of the most useful tools ever designed.

This tool is the only really effectual foot drill on the market.



A tool that will earn its cost many times over. :: :: ::

Surface of Table Top,	23″ x 12″	Sensitive movement,	4½″
Surface of Wings, -	23″ x 10″	Radial movement of arm,	120°
Travel of head on arm,	18″	Height over all -	5′ 10″

AGENTS. WE ARE LOOKING FOR FIRMS WILLING TO TAKE UP AGENCIES. WRITE TO

DRUMMOND BROS., Limited

Reid Hall, Guildford, Surrey, England

The advertiser would like to know where you saw his advertisement—tell him.

Orangeville, Ont.—The ratepayers are being asked to grant a loan of $3,000 to aid a novelty manufacturing concern to establish here.

Waterloo, Ont.—Snyder Bros. are building a new furniture shop heer at a cost of $15,000. Upholstered goods will be manufactured.

St. John, N. B.—P. M. Black, of Portland, Me., announced recently that a factory is to be established here for the manufacture of Blockite, an explosive to take the place of dynamite.

Regina, Sask.—It has been reported that a large eastern firm will establish a soap factory here in the near future.

Halifax, N. S.—Fire destroyed the boiler house of the Carritter, Paterson Mfg. Co.'s roofing paper works at Fairview recently.

New Westminster, B. C.—The Dominion Match Co. have secured a site here, and will erect a $75,000 plant. It will be 200 x 60 feet.

Montreal, Que.—It has been announced that Swift & Co. will locate here, and erect a big storage plant. This will necessitate the installation of a refrigeration plant.

Toronto, Ont.—Scythes & Co. have purchased a factory on Macdonnell Avenue for $13,000.

Ottawa, Ont.—The publicity commissioner has received a communication from a firm of cut glass manufacturers, who intend opening here shortly.

Guyon, Que.—Fire did $10,000 damage to the Dawd Milling Co.'s mill here recently.

St. Aandrews, N. B.—The Canadian Sardine Co. will erect a large plant at Chancook, near here. G. F. Johnson, of Montreal, is the president.

Chatham, Ont.—D. A. Gordon, of Wallaceburg; Gilchrist, of Detroit, and, Alpena, Smith, of Bay City, and Averey, of Detroit, propose establishing a sugar beet factory here. The plant, if erected, will be one of the largest in the Dominion, having a capacity of 1,000 tons per day.

Kingston, Ont.—The Commercial Box & Envelope Co. are asking certain concessions from the city, to aid them in establishing here.

Wallaceburg, Ont.—The town is being asked to grant aid to the Wallaceburg Glass Co., by extending a loan of $20,000.

Kincardine, Ont.—The Andrew Malcolm Furniture Co. are asking for partial tax exemption to assist them in locating their industry here.

Mount Forest, Ont.—The ratepayers carried the by-law to aid the Carriage Co. by granting a loan of $14,000.

Oakville, Ont.—The tax exemption by-law in favor of the Ware Mfg. Co. was carried by the ratepayers.

Granby, Que.—The burgesses carried the by-law to loan the Granby Hardware Co. the sum of $5,000.

Calgary, Alta.—The Flesher Marble Co. will erect a plant here.

Toronto, Ont.—W. B. Levack is about to erect a $13,000 tannery here.

THE AMERICAN ABELL CO.

The M. Rumley Company, of Laporte, Indiana, has purchased the stock and assets of the American Abell Co., of Abell street, Toronto, for a sum slightly in excess of two million dollars. The purchasers will continue to carry on business here under the American Abell name, but will in the near future double the capacity of the plant, which they have acquired to get entrance into the Canadian agricultural machinery market. The American Abell Co. is incorporated under Ontario laws, and has an authorized capital of $1,000,000, of which $700,000 has been issued, consisting, it is understood, of $500,000 common stock and $200,000 preferred.

THE PARSONS TURBINE IN CANADA.

Mr. J. P. Stockbridge, who represents G. S. Parsons & Co., Newcastle-on-Tyne, is visiting various parts of Canada in the interests of their turbine which has such a wide application for driving generators, ventilating fans, etc. Mr. Stockbridge has recently been engaged in the installation of many large Parsons turbine plants in Australia. One of the principal results of his present visit has been the placing of the sole Canadian agency for these turbines with the Robb Engineering Co., who will also manufacture certain parts. The Robb Engineering Co., with offices in the principal cities of Canada, are the well-known contractors for the complete equipment of central power stations, collieries, steel works, etc.

THE CANADIAN ELECTRIC WELDING CO., LTD.

A company to be known as the **Canadian Electric Welding Company, Ltd.,** has recently been organized. The capitalization is $500,000, and the headquarters in the Bank of Ottawa Building, Montreal. It owns and will operate in Canada, the patents covering spot or point

The JOHN MORROW SCREW, Limited, INGERSOLL

welding of the Universal Electric Welding Co., New York, and the Thomson Electric Welding Co., Lynn, Mass. The vice-president and general manager, A. M. Irvine, is well known as the late managing director of the Parker Foundry Co., Montreal, and the other directors of the company are:—Robert Hobson, vice-president of the Steel Company of Canada; W. W. Butler, vice-president of the Canadian Car & Foundry Co.; C. W. Kinsella, contractor, New York, and A. J. Nesbitt, Montreal. With the unlimited possibilities for electric welding, and with the strong baord which this company has secured, it will no doubt attain a high degree of success in its undertaking.

TRADE NOTES.

The Robb Engineering Co. have recently sold return tubular boilers as follows: One 48 in. x 12 ft. to Albert Fraser, Clementsvale, N.S.; one 42 in. x 10 ft. to Frank L. Irving, Billtown, N.S.; and a 42 in. x 10 ft. heating boiler to Gorman, Clancey & Grindley, Edmonton, Alta.

The Goodyear Tire & Rubber Co., of Canada, Ltd., have just completed a very large addition to their factory at Bowmanville, Ont. It involved an expense of $170,000, which includes a new three storey building and additional machinery. This will greatly increase their capacity for the manufacture of Rubber Goods. The difficulty in the past year has been that their previous factory equipment was not sufficient to keep up with the orders which were received. Special machinery of the latest and most modern type for the manufacture of Mechanical Rubber Goods has been installed. The large Hose room is so constructed that there are no posts to obstruct the working of the overhead carriers. The labor question has been a serious one, especially due to the fact that there was no accommodation for help. It has been decided to build about sixty workmen's cottages; 26 of these being now under construction, and more will be added as soon as possible.

The Youngstown Sheet and Tube Co., Youngstown, Ohio., has recently placed an order with the **Westinghouse Electric and Manufacturing Co., East Pittsburg, Pa.,** for a total of 99 motors to be used in connection with their open hearth plant. They will be used on cranes, charging machines, strippers, transfer tables, screw downs and blooming mills. The Youngstown Company formerly used the Bessemer Process, and is now installing the open hearth process and blooming mill for taking care of the open hearth process output. An interesting point of this order is that 56 of these will be the new Westinghouse M.C. direct-current mill type motor, equipped with commutating poles. This line has been designed to parallel the well-known M.T. alternating-current motor which has proved so successful in mill service.

The Hamilton Facing Mill Co., Hamilton, Ont., have recently sold and installed cupolas at the following plants:—The Waterous Engine Works Co., Brantford; The Canadian Yale & Towne Co., St. Catharines; The Kerr Engine Co., Walkerville, and that of Thomas B. Angrove, Kingston, Ont.

The Smart-Turner Machine Co., Hamilton, Ont., report the following orders recently received:—Messrs. Parke, Blackwell & Co., Toronto; Independent Jet Condenser, The Hollinger Gold Mines, Ltd., Aura Lake, Porcupine; Automatic Feed Pump & Receiver, The Royal Ice Cream Co., Welland, centrifugal pump; The Niagara Braud Spray Co., Trenton, duplex ball valve pump; Messrs. Price Bros. & Co., Jonquiere, P.Q., two power vacuum pumps; New Brunswick Pulp & Paper Co., Millerton, N. B., duplex pot valve pump; The Dominion Government, two vertical duplex donkey pumps; The Davis Leather Co., Newmarket, duplex pump; The Alabastine Co., Caledonia, duplex double acting power pump; The Foley-Rieger Pulp & Paper Co., Thorold, centrifugal pump.

POWER PLANT DEVELOPMENTS.

BRITISH COLUMBIA.

Kamloops.—Superintendent C. L. Wain reports as follows on enlargment and additions to power plants:—A new pump is required, capacity 2,000,000 gals. a day. Recommendation was made for a 2,000,000 gallon reservoir with a 14-inch supply pipe. Total cost of installation was estimated as follows: Turbines, pumps, boilers, etc., $53,150; pipe line, gates and valves, $23,701; reservoir (1,000,000 gals.) $19,132.92; reservoir (2,000,000 gallons) $31,276.17. Total cost with reservoir of one million gallons, $95,983.92. Total cost with reservoir of two million gallons, $108,227.47.

MANITOBA.

Winnipeg.—Tenders will be received until January 22nd, 1912, for the supply of one 250 k.w. exciter motor generator set, with accessories complete, and spare parts, to be

erected on foundations supplied by the corporation in the power house, Point du Bois. Further instructions may be had at the office of the Power Engineers, Carnegie Library Building, Winnipeg.

ONTARIO.

Sault. Ste. Marie.—The Lake Superior Power Co. have awarded the contract to Chapman & Walker, Toronto, for the supply of electric motors, amounting to 3,000 h.p., and costing $30,000.

Carleton Place.—On January 1st a by-law to raise $200,000 for a waterworks system was voted on.

Kincardine.—An extension to the filtration system is proposed, and the engineer is instructed to report on present system and cause of scarcity of water.

Ottawa.—A by-law will be submitted to endorse an expenditure of $2,300,000 to bring water from McGregor's Lake.

Hamilton.—The city will apply for permission to borrow funds as follows:—Water mains, $74,469; check valves, $3,000; new shops, $1,000; beach pump house improvements, $1,000; new high-pressure boilers at Burlington Beach, $12,000; meters, $6,000; new conduit, $8,861; high-level reservoir improvements, $4,500; new services, $10,000; mountain pump house improvements, $500; piles at intake pipe, $800; new hydrants, $1,000. Total, $123,130.

Ottawa.—An artificial ice plant is to be installed in connection with the Chateau Laurier before the building is completed. The plant will be situated in the rear of the Grand Trunk station and will provide ice for both the station and the hotel. The architects, Ross & MacFarlane, say that the plant will be ready for operation as soon as the hotel is completed.

Ottawa.—Three rapids in the St. Lawrence River entirely on Canadian territory, the Cedars, Cascades and Coleau, are to be developed for water purposes, by an English syndicate. The promoters will capitalize their enterprise at $100,000,000, with a charter from the Dominion Government.

Brantford.—The Brantford Cold Storage Co. will equip a new plant.

Tavistock.—The work upon the new waterworks for the town having been practically completed, an exhaustive test was made recently by F. W. Farncomb, C.E., of London, who designed and supervised the construction of the system. The hose was attached to the hydrants at various points, and in every instance, the results were most satisfactory. Without using the pumps a uniform pressure of over 50 pounds was secured from the 50,000-gallon elevated tank. This will be the constant domestic pressure. With the pumps in operation a pressure of 115 to 125 pounds was maintained. This pressure will only be used in case of fire. The steam pumps, which were supplied by the Canadian Fairbanks Company, have a capacity of half a million gallons each, and are abundantly supplied from two large overflowing artesian wells to the north of the town. The water is conveyed by gravity to the pumphouse, from whence it is lifted through the pumps into a steel tank elevated to a height of 120 feet. In case of fire the tank may be cut off and the water forced directly into the mains. Automatic relief valves are connected with the mains, so that with both the powerful pumps in operation, should the fire hydrants be closed, the pressure will not exceed 100 pounds. The water mains, which were laid by Messrs. Craig & Geary, of London, developed no leaks under the pressure.

QUEBEC.

Montreal.—The power house and electric supply station of the Saraguay Electric Co. was visited by fire recently. The fire, it is believed, had its origin in the boiler room, which is separate from the station proper, but soon made its way to the latter building. Both structures were badly damaged. The buildings were erected in 1904. They are of concrete and cement construction, the only woodwork being some interior fittings. The capacity of the Cartierville plant is 30,000 h.p., and many of the new wards of the city depend on this plant for electrical energy in connection with street lighting.

Quebec.—Municipal lighting and erection of a steam plant, etc., will be rushed in Quebec, and probably new machinery installed for extra power at the dam at Dorchester, 15 miles from here. Contractor, The Dorchester Electric Co., of Quebec.

Montreal.—In connection with installation of pumps for the sewage disposal plant here, the following are the tenders submitted:—John McDougall, Caledonian Iron Works, $29,300 and $30,400; Chapman & Walker, $23,100 and $24,500; John Inglis Co., $25,300; Canadian General Electric Co., $22,600; Laval Steam Turbine Co., $27,000. In the case of Chapman & Walker and John McDougall,

All weights up to 6,000 lbs.
We make a specialty of difficult cored work
LET US FIGURE ON YOUR REQUIREMENTS
GALT FOUNDRY CO, GALT, ONT.

Caledonian Iron Works, two separate types of pumps were quoted on.

Montreal.—Following the completion of its freight yards at the Place Viger station, the C. P. R. has now begun work on the laying out and construction of another huge freight terminal for Montreal to take care of most of the work now done at the terminals at Outremont. The new yards are to be situated some distance west of Montreal, and the name of the station, it has been decided, shall be Sortin. Announcement was made that the contract has been awarded for the construction of a 24-stall engine house, machine shop, turntable, coaling plant, stores and rooming and lodging building, the latter capable of accommodating 100 men. The new yards will have an initial capacity for 2,000 cars and eventually that for 4,000, and will be among the largest and most complete in the Dominion. They will save a haul on the traffic, as compared with the Outremont yards, of 20 miles.

Montreal.—A check, the amount of which was not disclosed, passed recently from the officials of the Canadian Light, Heat and Power Co. to those of the Saraguay Electric and Water Co., thus closing a deal which has been on the tapis for some time past. The Saraguay Company was brought into official existence in the year 1906, the capital being authorized to the extent of $3,000,000, and it is stated that the amount expended on the plant amounts to close on to three-quarters of a million dollars. It has over six hundred customers within the city limits, and about 1,000 in all, so it will be seen that a formidable clientele has been transferred to the Canadian Light and Power Co. The latter also acquired control of the Central Heat, Light and Power Co. last spring.

Montreal.—The contract for the installation of the first two units for the development and transmission to Montreal of 40,000 h.p. of electrical energy from Carillon Falls has been given to the Carillon Construction & Development Co., Montreal, by the National Hydro-Electric Co. The work of this contract began on November 20th.

Montreal.—The Bishop Construction Co., Montreal, has ben awarded the contract for the construction of the dam power house of the hydro-electric power plant on the Magog River at a cost of $125,000. T. Pringle & Son, Ltd., engineers and architects, 419 Coristine Bldg., Montreal.

Lake Megantic.—The Lake Megantic (Que.) Pulp Co. will buy turbine engines for a new power plant to be built on the Chaudiere River, at Lake Megantic.

NEW BRUNSWICK.

Edmundston.—The town of Edmundston recently inaugurated its electric plant, when Mayor A. Dugal, in the presence of the aldermen of the town and Pius Michaud, M.P., turned on the electric current. The generating station for both the water and the electric plants with capacity of 450 h.p., is situated on Green River, ten miles north of Edmundston, and consists of a dam 400 feet long and 28 feet high, a power house with two sets of twin water wheels and two electric generators. It can supply sufficient power for water distribution and electric lighting to a population of at least 10,000 inhabitants. The streets are lighted with 150 tungsten lamps, each having a capacity of 65 candle power. The capacity of the steam pump is 700 gallons per minute, and that of the electric pump, 1,200 gallons to the minute. On the highest point of the town is located a steel stand pipe 35 feet in diameter and 50 feet high, having a capacity of 35,000 gallons which gives a natural water pressure of 125 pounds. Forty-four hydrants for fire protection are distributed over the town.

CATALOGUES.

Circular 1198, describing Alternating-Current Water-Wheel Generators has been issued by the **Westinghouse Electric and Manufacturing Co., of East Pittsburg, Pa.** The publication illustrates and describes the different types of generators, both vertical and horizontal, for water-wheel drive, manufactured by that company. It appears that the Westinghouse Company has several different types of rotor construction each of which is adapted for a certain rotor diameter and speed range. These types of construction are described in considerable detail. Other components of the water-wheel generators are given attention and many pictures of installations are shown. Numerous illustrations of water-wheel driven installations are shown.

Plastics, Ltd., Van Horne St., Toronto, have sent us a copy of their Catalogue E-F in which are listed their well-known Bakelite discs for globe valves and Bakelite pump valves. Bakelite is a new product that cannot be softened, fused or cracked by moisture,

steam or chemicals and is meeting with much success.

Fyfe, Wilson & Co., Glasgow, Scotland, have sent us their Bulletin No. 112, which describes the Kelvin gasoline and kerosene-driven electricity generating sets. These have been designed for use in lighting farm and country houses, hotels, etc. In the Kelvin set, the engine is direct connected to the dynamo, the whole being mounted on one bed. The four-cycle or Otto principle has been adopted. The engine is fitted with the Bergins starting device, by means of which starting up without vigorous cranking is accomplished. Each generator set includes a storage battery of sufficient capacity to carry the lighting load under normal conditions for several days at a time—even during the darker season of the year. It is, therefore, only necessary to run the engine once or twice a week for a few hours. The various sets mounted on wooden trucks, with four small wheels, are readily portable by hand or horse haulage. The sizes vary from 3 to 16 kw.

Veritys, Ltd., Aston, Birmingham, England, have sent us illustrated price lists of their English-made Tungsten lamps, and also of their Aston Farm House lighting sets. These consist of a gasoline engine and a dynamo direct-coupled and mounted on one base. An accumulator and switchboard complete an outfit, which it to be recommended on account of its easy portability. These sets are supplied in six sizes, suitable for from 28 to 225 lamps of 20 watts. Prices are quoted in Canadian currency, and are very reasonable.

The Vincit Company, Ltd., 70 Queen Victoria St., London, E.C., England, have issued a catalogue of their carborundum and electrite grinding wheels, hones, discs, powders, etc. Carborundum, of course, needs no description. Electrite, another product of the electric furnace, is claimed to be particularly suitable for grinding steel, brass, copper, gun metal, malleable iron, etc.

The Westinghouse Electric & Manufacturing Co., East Pittsburg, Pa., have sent us their circulars No. 1028 and 1190. The first illustrates and describes numerous examples of rotary converters, while the second deals with type E engine-driven A. C. generators.

The Allis-Chalmers Co., Milwaukee, Wis., have forwarded a copy of their Bulletin No. 1083, setting forth the distinctive features of their D. C. generators and showing numerous examples of their application to the direct driving of machine tools.

The Wirt Electric Specialty Co., Germantown, Penn., call attention in Bulletin 1106, to their various types of electrical resistance units, which are insulated with a patented material known as "Di-el-ite."

The Canadian Gasket Co., Bridgeburg, Ont., send us their price list of gaskets. Among other types listed are plain and corrugated copper gaskets, those with asbestos cord filled corrugations, smooth copper gaskets with asbestos filling, lead gaskets for ammonia fittings, oval gaskets for man-holes, hand-holes, etc.

Poetter, G. M. B. H., Ltd., Dusseldorf, Germany, have sent us a copy of their latest catalogue of gas producers, constructed on the Hilger system. These producers have a slowly rotating ash pan and a star shaped grate. Through the rotation of both of these the ash in the producer is kept constantly in motion, thus preventing formation of clinker. Moreover, by these means new surfaces of the fuel are being constantly brought under the influence of the blast, with the result that gasification is greatly hastened. A gas producer of 10 feet internal diameter is claimed to be capable of dealing with 25 long tons of coal or 36 tons of lignite per 24 hours.

Veritys, Ltd., Aston, Birmingham, England, have sent us their List No. X119, which describes handy farm house lighting sets, consisting of a dynamo and gasoline engine direct-coupled and mounted on one base.

The Lunkenheimer Co., Cincinnati, Ohio, has recently issued an attractive booklet describing their various types of blow-off valves, and they will be pleased to send it upon request.

The Keuffel & Esser Co., New York, and Montreal, have mailed us their latest price list of flat wire tapes and band chains for the use of surveyors, contractors, etc.

George Swift & Sons, Halifax, England, have favored us with a copy of their new catalogue No. 151, which deals with the high speed engine lathes manufactured by this firm. These are at present made in four sizes: 7, 8½, 10 and 12½-inch. The 7-inch lathe has a cone drive, and the others can be supplied with cone drive or all-geared motor-driven head, if desired. The designs are thoroughly up-to-date, and prospective pur-

chasers should have the firm's catalogue on file.

The Allis-Chalmers Co., Milwaukee, Wis., have forwarded a copy of their Bulletin No. 1083, setting forth the distinctive features, and showing numerous examples of the application of their D. C. generators to the direct driving of machine tools.

The Hendey Machine Co., Torrington, Conn., have brought out a booklet entitled, **"Helps on Change Gearing and Thread Cutting for Users of Hendey Lathes,"** which they will be glad to send to all operators and purchasers of their lathes.

CATALOGUES RECEIVED.

A. A. Jones, Pollard & Shipman, Leicester, England, have sent us their latest catalogue of machine tools. These include high speed drilling machines from 20 up to 30 in. swing, milling machines, drill grinders, tool and cutter grinders, power hack saws, arbor presses, etc., etc. Many of the lines have been specially brought out to meet competition on the Canadian market, and the designs appear to be thoroughly sound. The makers guarantee the accuracy of their sensitive drills to .001-inch, and of their upright geared drills to .002-inch. Users of machinery would be well advised to send for this catalogue, more especially as the prices quoted are most attractive.

The Kearney & Trecker Co., Milwaukee, Wis., have brought out Catalogue 18, dealing exhaustively with the well-known Milwaukee milling machines. The catalogue is a high-class production, and contains a large amount of useful information concerning the construction, upkeep and operation of these products. Tool room and machine shop foremen, etc., can secure a copy on application.

BOOK REVIEWS.

Under the title "Technology and Industrial Efficiency," the proceedings of the Congress of Technology, held in Boston last April, at the Massachusetts Institute of Technology, have been published in a volume of about 500 pages. Some seventy papers are included, and these form a valuable and up-to-date record of the present state of industrial science, together with a presentation of some of its problems and probable solutions. The six sections, into which the congress was divided, are represented by papers on: Scientific Investigation and Control of Industrial Processes; Technological Education in its Relation to Industrial Development; Administration and Management; Recent Industrial Development; Public Health and Sanitation; Architecture.

A Short Course in the Testing of Electrical Machinery, by J. H. Morecroft and F. W. Hehre, New York, D. Van Nostrand Co.; price $1.50. This book has been written primarily for the use of engineering students who are not specializing in electrical work, but who nevertheless desire to obtain some knowledge of testing. There are many operating engineers desirous of obtaining a knowledge of theory to whom this book should prove useful.

The "Mechanical World" Electrical Pocket Book for 1912; Emmott & Co., 65 King Street, Manchester, England; price 12 cents. Various improvements have been made in the latest edition of this popular little handbook. The matter devoted to lighting has been entirely re-written, and is now presented in two sections, one dealing with electric lamps, and the other with electric lighting. A new section on motor starters has been introduced, and another on static transformers. The book throughout has been generally revised, and as usual is worth many times the low price asked for it.

Bulletin No. 48, "Resistance to Flow Through Locomotive Water Columns," by Arthur N. Talbot and Melvin L. Enger, records the results of tests of fourteen of the principal forms of locomotive water columns or cranes in use on the railways of the United States. Besides giving the loss of head at various rates of discharge, the tests provide data on the hydraulic characteristics of the valves. Water hammer, relief valves, friction losses through pipe lines, and methods to be used in the design of water service installations are also considered. The bulletin should be of interest to motive power and maintenance of way men. Copies of this bulletin may be obtained gratis upon application to W. F. M. Goss, Director of the Engineering Experiment Station, University of Illinois, Urbana, Illinois.

"Tests of Nickel-Steel Riveted Joints," by Arthur N. Talbot and Herbert F. Moore has just been issued as Bulletin No. 49 of the Engineering Experiment Station of the University of Illinois.

The use of nickel-steel in the construction of bridges of great span is one of the interesting recent developments in the field of engineering. For many years it has been known that an alloy of nickel with steel possessed great strength and toughness, and hence nickel-steel has been extensively used as armor for battleships, and in other structures where the necessity for great strength was paramount.

To the casual observer, a steel bridge seems to be a rigid structure, but the engineer knows that microscopic movements of parts are constantly taking place as the bridge is exposed to wind, to heat and cold, or to the moving load of a passing train. There is no doubt that the use of nickel-steel would make possible the reduction of the weight of steel required to build a bridge, but the action of the riveted joints of the bridge, if nickel-steel were used, has not been known.

In considering designs for a new bridge over the St. Lawrence river, near Quebec, Canada, which is to replace the bridge that collapsed during the erection, the Board of Engineers of the Quebec Bridge, appointed by the Canadian Government, requested the Laboratory of Applied Mechanics of the University of Illinois to undertake a series of tests of nickel-steel riveted joints.

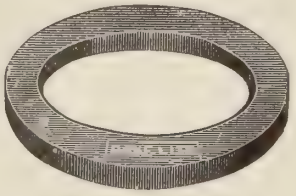
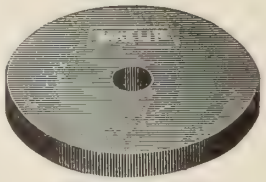
These are the telling points about



Bakelite

Valve Discs

THEY will not leak under high temperature, excessive pressure or when used in acids or other special liquids. Neither cold water, dry or superheated steam has the least effect upon them. BAKELITE Discs are a gas-tight fit



BAKELITE is a successful substitute for expensive metal. Its structure is fibrous, giving strength and hardness. It can be reground and refaced, always retaining a uniform surface. It cannot be injured except by accident or friction.

Remember Bakelite PUMP VALVES do not warp with changes of temperature.

Order your valves fitted with Bakelite Valve Discs and stop that perpetual annoyance and expense caused by leaking valves. Depend upon it, Bakelite Valve Discs will not leak.

Write for prices or ask your dealer.

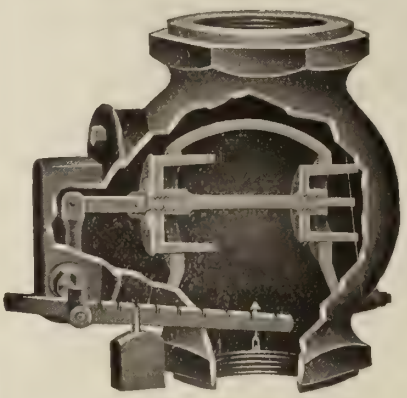
Double Seated Noiseless Back Pressure Valve



The construction of the inner Valve and seats is of such a nature that uneven expansion of the metals will not cause the Valve to STICK or BIND—A FEATURE which places this Valve in a class by itself. ANOTHER FEATURE of our Back Pressure Valve is that it can be placed in ANY POSITION.

It is a DISTINCT improvement on the OLD STYLE single seated Valve. It has a DOUBLE PISTON TYPE of inner Valves, with disc of different area.

Guaranteed close regulation without excessive weighting. Carried in stock from 2 to 16 inches.

MORE AIR
FOR THE MONEY

The class "NE-1" compressor delivers more air for the money invested and the power consumed, month after month, than any small compressor heretofore offered. It should, however, it's manufactured to be a leader. It embodies all the modern ideas in air compression.

The "NE-1" is obviously an aristocrat. When you consider its construction: the large, amply oiled bearings, the perfectly balanced rotating and reciprocating parts; the large, free air ports; the high grade workmanship and many other features which it embodies, and which are detailed in our Pamphlet K-92, you will agree with us that it is a superior little machine.

McEWEN ENGINES

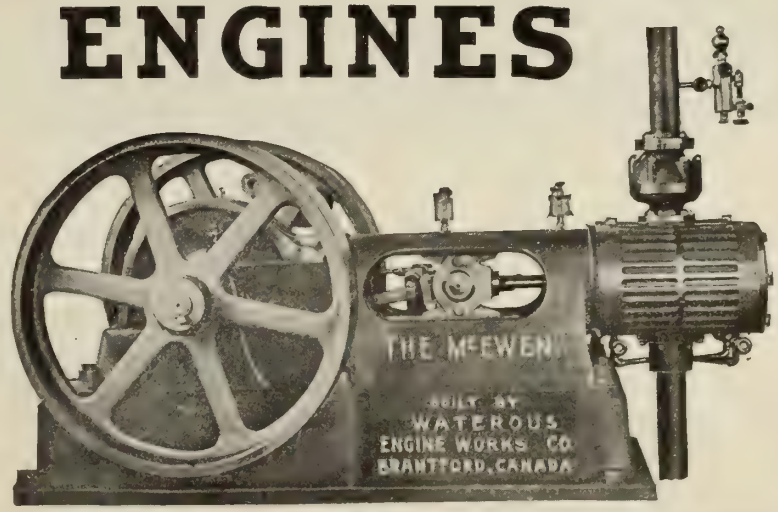
High Speed — Automatic

Built for simplicity, accessibility, close regulation and general reliability under trying conditions. They are smooth running, require little attention, and are quick and sensitive in regulation under full load or when running light.

A heavy rigid bed. Cross head guides, main bearings, and face for cylinder attachment machined at one operation. All parts are in perfect line and will stay so. Piston type valve, double ported, frictionless. Balancing pressure plate slotted to correspond with valve seat. A quicker, more powerful stroke by providing double admission and exhaust edges. Automatic Begthrup Inertia Governor.

Built in simple or compound units of from 10 to 700 H.P.

Get our McEwen Engine Catalogue.



HERE IS OUR GUARANTEE:

"The engine shall not run one revolution slower when fully loaded than when running empty, and a reduction of boiler pressure from the greatest to that necessary to do the work will not reduce the speed of the engine one revolution. Any engine failing to meet this guarantee becomes the property of the purchaser upon payment of one dollar."

will take over the entire Canadian business.

Nothing Counts Like Goodhue Service

If you want a particular kind of Belting service, a service that is absolutely reliable, economical and efficient, we guarantee

Goodhue Belts

to meet your requirements satisfactorily.

They stretch from 15 to 25 per cent. less than other belts, which is due to the extra care given to stretching the leather before the belt is made up and the rejection of all unstretched parts.

This 15 to 25 per cent. less stretch means 15 to 25 per cent. less time required to tighten the belt—this saving should appeal to every belt user.

According to the conditions where the belt has to run, we recommend our "EXTRA," "STANDARD," or "ACME WATERPROOF" BELTS.

Write at once and let us demonstrate how we can save you money.

J. L. Goodhue & Company, Ltd. Danville, Quebec

THERE'S A COPY FOR YOU

If you are interested in selling a line of power transmission appliances that has strong talking points, that has distinctive merit, that has unique individuality, that appeals to manufacturers because it embodies the perfection of modern principles of power distribution and control; or if you are a manufacturer and contemplate using any new power transmission equipment, you want this catalogue, "The POSITIVE Line."

You can't afford not to investigate POSITIVE Combined Jaw and Friction Clutches, Combination Split Pulleys, Shaft Hangers, Pillow Blocks, Compression Shaft Couplings, etc., if you want to handle or use the line that is so entirely different, better and far in advance of existing designs of such appliances, that it has revolutionized the transmission of power in manufacturing plants and has established a higher standard of dependability, durability, economy and efficiency in industrial operations.

The catalogue also contains some handy engineering tables and formulae. When you ask for it, don't fail to state, "Second edition of The POSITIVE Line."

Not an Enterprise for the "Quitter"

"If there is one enterprise on earth," says John Wanamaker, "that a 'quitter' should leave severely alone, it is advertising. To make a success of advertising one must be prepared to stick like a barnacle on a boat's bottom

"He must know before he begins it tha he must spend money—lots of it.

"Somebody must tell him that he cannot hope to reap results commensurate with his expenditure early in the game.

"Advertising does not jerk; it pulls. It begins very gently at first, but the pull is steady. It increases day by day and year by year, until it exerts an irresistible power."

Machinery Wanted and For Sale

AGENTS WANTED.

AGENTS WANTED—English firm manufacturing lifting tackle of every description and with merchant department for handling all classes of engineering material want Agents in Canada. Box 75, MACHINERY AND MANUFACTURING NEWS, 88 Fleet Street, London, England.

SITUATION VACANT.

WANTED—Engineer with good practical experience in all classes of interior lighting and motor installation. Special duties revising rules and regulations. An engineer with English and European experience preferred. HYDRO-ELECTRIC POWER COMMISSION, Continental Life Building, Toronto. (9)

WANTED—A good nickel-plater for a stove concern. Good wages; steady job. Apply "Plater," CANADIAN MACHINERY, Toronto.

BELTING, PACKING, ETC.

BELTING FOR SALE—800,000 feet of best quality leather, rubber, hair and canvas belting, bought from bankrupt manufacturers at 25% to 75% less than the regular value. Also a large quantity of slightly used belting, piping, chains, rails, pulleys, hangers, cotton waste, etc., at very low prices. Send for catalogue. IMPERIAL BELTING AND SUPPLY CO., 5 Queen Street, Montreal.

BELTING, RUBBER, CANVAS AND LEATHER, Hose Packing, Blacksmith's and Mill Supplies at lowest price. N. Smith, 138 York Street, Toronto. (2tf)

MACHINERY FOR SALE.

MACHINERY FOR SALE—New and Second-hand Machinery, Engines, Boilers, Wood and Iron Working Machinery and Supplies. Write, stating what you require. Prompt and careful attention to all inquiries. THE ADVANCE MACHINE WORKS CO., Montreal, Que.

FOR SALE—Two Goldie-McCulloch Boilers in good repair—length 14 feet, diameter 5 feet, 74 3-inch flues, 70 h.p. GARLOCK PACKING CO., Hamilton, Ont.

FOR SALE—About 25 60-cycle 110-volt flame lamps, complete with individual transformer. First-class condition. Allgemeine-Gesellschaft type. Changing to 25 cycles. Excellent bargain if sold in one lot. A. H. W. JOYNER, 76 Bay Street, Toronto.

MANUFACTURING CENTRES.

FREE FACTORY SITES—Seven railroads, deep water, Niagara power, natural gas, low taxation, abundant labor. Welland, Ontario. B. J. McCormick. (12y)

POSITIONS WANTED.

FOUNDRY SUPERINTENDENT OR FOREMAN is open for position. Up-to-date in general foundry practice, chemical analysis, molding machines, also automobile castings. Can give results. Apply Box 115, CANADIAN MACHINERY, Toronto

FOREMAN DIE AND TOOL MAKER, experienced in handling men in die and tool room, thorough knowledge of manufacturing and plating department, brass fixtures and stamped work. Apply Box 113, CANADIAN MACHINERY, Toronto.

POSITION WANTED—Executive position. One with broad experience in factory efficiency, up-to-date methods, ability, and a good organiser. Wishes to correspond with parties. Box 114, CANADIAN MACHINERY, Toronto. (9)

WANTED.

WANTED — Every Power House in Canada to remember that C. E. Shedrick, Craig Street West, Montreal, is still repairing measuring instruments, both switch board and portable. Twenty-five years' experience in repairing all kinds and makes on the market. Intregating meters repaired, tested and sealed, and returned on quick time. (12y)

PATENTS FOR SALE.

IRON PURIFICATION PROCESS. — Owners of U.S.A. and Canadian Patents of The Johnson Iron Process for producing superior iron castings at low cost, which is a proved success in England, are desirous of disposing of the above Patents or either of them or of granting licences to use the same in U.S.A. and Canada. Full particulars will be supplied to any bona fide applicant by the owners. VERDON CUTTS & HOULT, 87 Fargate, Sheffield, England. (9)

MISCELLANEOUS.

A BOOK-KEEPING STAFF IN ITSELF — doing the work with machine-precision and accuracy, the National Cash Register. Write us for demonstration literature. National Cash Register Co., 285 Yonge St., Toronto.

COPELAND-CHATTERSON SYSTEMS — Short, simple. Adapted to all classes of business. Copeland-Chatterson Co., Limited, Toronto and Ottawa. (tf)

COUNTER CHECK BOOKS — Write us to-day for samples. We are manufacturers of the famous SURETY NON-SMUT duplicating and triplicating Counter Check Books, and Single Carbon Pads in all varieties. Dominion Register Co., Ltd., Toronto.

DOUBLE YOUR FLOOR SPACE. An Otis-Fensom hand-power elevator will double your floor space, enable you to use that upper floor either as stock room or as extra selling space, at the same time increasing space on your ground floor. Costs only $70. Write for catalogue "B." The Otis-Fensom Elevator Co., Traders Bank Building, Toronto. (tf)

ELLIOTT-FISHER STANDARD WRITING-ADDING MACHINES make toil easier. Elliot-Fisher, Limited, Room 314, Stair Building, Toronto.

FIRE INSURANCE. Insure in the HARTFORD. Agencies everywhere in Canada. (tf)

MODERN FIREPROOF CONSTRUCTION—Our system of reinforced concrete work, as successfully used in many of Canada's largest buildings, gives better results at lower cost. "A strong statement," you will say. Write us and let us prove our claims. That's fair. Leach Concrete Co., Ltd., 100 King St. West, Toronto. (tf)

MR. BUSINESS MAN, are you progressive? It's up to you to test "Consolidated," our new process carbon paper. Because it costs less. Soft finish, without smutting, and clear, permanent copies. Write for sample sheets and prices. "Consolidated," Stratford, Ont.

FROM NOW TILL THE END OF THE YEAR we offer unusually good bargains in second-hand Typewriters. They are carefully rebuilt, work and look like new, but the price is a mere fraction of the original cost. Write for catalogue. THE MONARCH TYPEWRITER CO., Limited, 46 Adelaide St. West, Toronto, Ont.

"SYSTEMS" stand for all that is best in loose-leaf binders and supplies, letter-heads, statements and in fact your office stationery of every description. Send us samples of what you are using—we will send you prices that will interest you. Business Systems, Limited, Manufacturing Stationers, Toronto. (tf)

THE "Kalamazoo" Loose Leaf Binder is the only binder that will hold just as many sheets as you actually require and no more. The back is flexible, writing surface flat, alignment perfect. No exposed metal parts or complicated mechanism. Write for booklet. Warwick Bros. & Rutter, Ltd., King and Spadina, Toronto.

WAREHOUSE and Factory Heating Systems. Taylor-Forbes Company, Limited. Supplied by the trade throughout Canada. (tf)

Write Now!

Our Furnaces Heat Steel with the Cheapest Fuel on Earth—

SOFT, SLACK COAL

They are all fired with "American" Mechanical Stokers, which burn bituminous slack coal automatically and without smoke, and give a clear, steady, soft, non-scaling flame. You get increased production, at about one-third to one-half the operating cost of oil or hard coal. This is a fact. If you burn money to heat steel why not burn less of it, and write us at once?

FREE INSTRUCTION BOOK

SEND FOR IT TO-DAY

This book should be within instant reach of every engineer. It tells clearly, by photograph and formula, how to use the well-known Smooth-On Iron Cements in repairing boilers, engines, castings, tanks, joints, etc.

Used according to instructions, Smooth-On Cements will save more actual time and money in the engine and boiler room than any single product manufactured. Their uses are innumerable, and their repairs absolutely permanent.

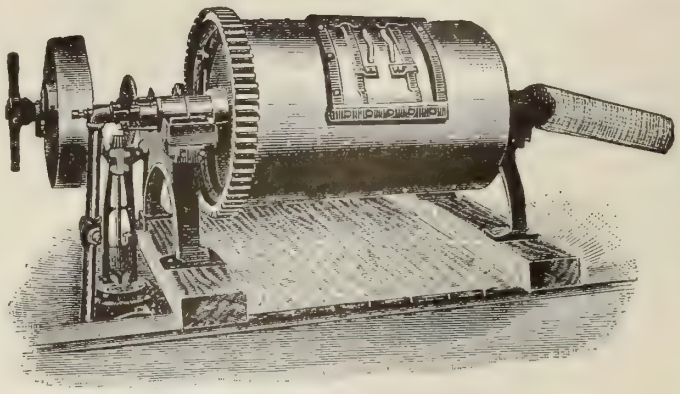
A GOLD MINE

SAVE YOUR IRON



SLY'S PATENT IRON CINDER MILL

Patented, No. 514097. Patented, No. 841728.

may be at your disposal on your very premises. Look out of your side window or back door and see if you have not an accumulation of cupola dump, and other foundry refuse, which is a total loss to you in its present state. Why not add to your profits and install one of the Sly Patent Cinder Mills to reclaim this iron and be astonished at your former loss and pocket the rich returns from your newly-discovered mine.

Sly's Patent Iron Cinder Mill will save 95% of the iron contained in your cupola dump and gangway scrapings and 75% of the coke. Iron is valuable, then why throw it in the dump? Iron recovered by this Mill is better than machinery scrap. Study economy in a foundry and your profits will increase accordingly. Mill will pay for itself three or four times every year, and we have records of Mill paying for itself twelve times a year. Let us know amount of your daily melt and we will quote. *Write for Cinder Mill Catalogue F.*

We also manufacture Cleaning Mills, Dust Arresters, Sand Blast and Foundry Equipment.

THE W. W. SLY MFG. CO., CLEVELAND, O.

The Making of Hollow Castings

The recent introduction of King Kore Kompound has now rendered this, once somewhat difficult, part of Foundry practice comparatively easy.

It has, also, reduced the core expense by more than one-half.

This compound is a black, dry powder, and is used as flour is used, but with one-half the quantity is produced greater and better results.

Its use avoids the danger of swelling or "blowing." The core easily comes out of the casting, and when old cores are ground up, in the rattler, or otherwise, the sand so made is used over again.

The core compound it contains, again becomes a binder under heat of the core oven, as it melts, and so it is used over and over again.

This is Foundry Economy; Flour, Rosin, etc., are now luxuries.

A barrel of King Kore Kompound will be sent "subject to approval" to any inquiring mind.

That is the Stevens' System of trying before buying.

I have copies of proportions of compound to sand used and methods followed in core rooms of Foundries in thirteen different States. This information, with other printed matter relative to the subject, will be mailed on request.

I maintain a direct branch at 137 Jarvis St., Mr. J. M. Mayers, Manager, Toronto, Ont., where is stocked a supply of Foundry Facings, Foundry Supplies, Buffing Compositions, of my own manufacture.

The stamp of quality pervades them all.

FREDERIC B. STEVENS

Main Office - - - - - - DETROIT, MICH.

Canadian Branch - - - 137 Jarvis Street, TORONTO.

STOP THAT LEAK

Drip, Drip, Drip ~
There Go Your Profits!

It's the Same Old Story

Another casting to be made over---another hole punched in your bag of profits. Every "make-over" means the jingling of escaping coins

WHY NOT ABOLISH MAKE-OVERS!

It's a very simple matter, *and we'll tell you how.* Just follow the example of the man in the illustration.

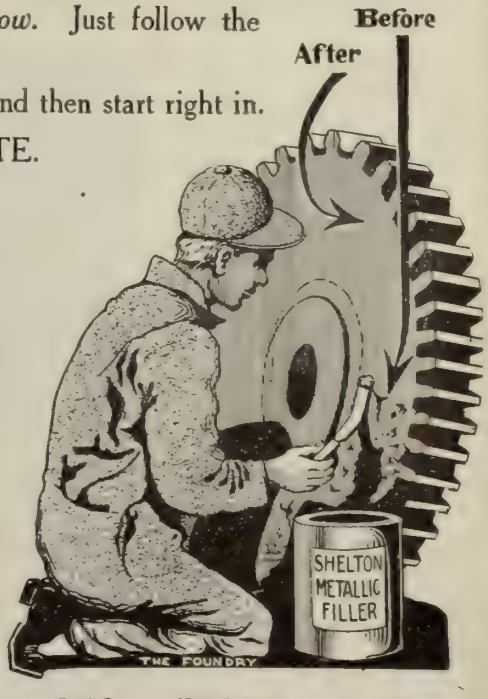
Get a can of Shelton Metallic Filler, a spatula---and then start right in.

DON'T CONTINUE A NEEDLESS WASTE.

Here is a chance to stop your losses.

Shelton Metallic Filler is guaranteed to fill in and completely obliterate blow holes, sand holes, etc. It becomes part of the casting itself, is durable, and can never be detected. It has been used with great success for many years.

Better write to us at once.



Save that Casting!

"Saving" a casting means *Changing Loss Into a Profit—a Prompt Shipment—Another Satisfied Customer.*

Can you afford to work handicapped?

Shelton Metallic Filler Co.,
DERBY, CONN.

ELECTRIC WELDING FACTS

A MANUFACTURER reports that three men and a boy with a welding machine are doing the work 17 men formerly did in riveting sled runners.

Another concern, making sheet metal boxes, say that one man with a welding machine is doing the work it required 10 men to do under their old method of riveting, and have reduced their costs 61%.

A wagon manufacturer electrically welds hub bands and saves 53% over the old way of fire welding.

A stove company paid $4.50 per 100 for riveting certain parts of their ranges. They now pay the same man 75 cents per 100, and he makes better wages than he could at riveting at the $4.50 rate, and does a better job.

Another manufacturer welds ears on sauce pans three welds per pan—and the boy turns out 650 dozen in 10 hours.

If you want to know more about the "saving way," get our new book just issued. It's free.

By Wm. C. Stimpson

Head Instructor in Foundry Work and Forging, Department of Science and Technology, Pratt Institute.

160 pp., 150 illus. Cloth binding. A practical guide to modern methods of molding and casting in iron, brass, bronze, steel and other metals, from simple and complex patterns, including many valuable hints on shop management and equipment, useful tables, etc.

Price, $1.00

Given free with four yearly paid-up subscriptions.

The subscription price is fifty cents per year; two years for one dollar.

Canadian Foundryman

143-149 University Avenue, Toronto

ELECTRIC SPOT WELDING

NO PUNCHING, REAMING OR RIVETING

Three operations made by one operation, and in less time than is necessary for either one of the operations named and with much less cost and greater efficiency.

Our machines are making as many as 13 welds in one operation.

Communicate with us and let us demonstrate advantages of our process and the reduction of your manufacturing cost.

CANADIAN ELECTRIC WELDING CO., LTD.

Bank of Ottawa Building - - - - MONTREAL, P. Q.

THE TAYLOR-NEWBOLD SAW
PATENTED
INSERTED TEETH IN THIS SAW TREATED UNDER EXCLUSIVE LICENSE BY THE TAYLOR-WHITE PROCESS.
MFD. & SOLD EXCLUSIVELY BY
THE TABOR MFG. CO.
PHILA. U.S.A.

Taylor-Newbold Inserted Tooth Cold Saw

Standard Type for Steel Foundry, Forge and Machine Shop Use.

Special Type for Cutting Rails and Structural Shapes.

The TABOR MANUFACTURING CO.

18th and Hamilton Sts. - - Philadelphia, Pa

OXY-ACETYLENE ∴

Oxy-Acetylene for Welding and Cutting Metals is the most efficient

THIS PICTURE SHOWS HOW OXY-ACETYLENE WAS USED IN CLEARING THE QUEBEC BRIDGE WRECK

14 PLANTS IN ACTUAL USE IN MONTREAL

OXY-ACETYLENE is used by Machinists, Electrical, Mechanical, Contracting, Hydraulic and Mining Engineers, Ship Builders, Structural Steel Workers, Iron and Steel Founders, Railroads and Street Railways, Automobile Manufacturers and Garages, and all Repair Shops.

The Greatest Known Heat by Combustion. No Chemical Change in Metals as with Other Systems

IN DAILY USE
IN THE FOLLOWING SHOPS

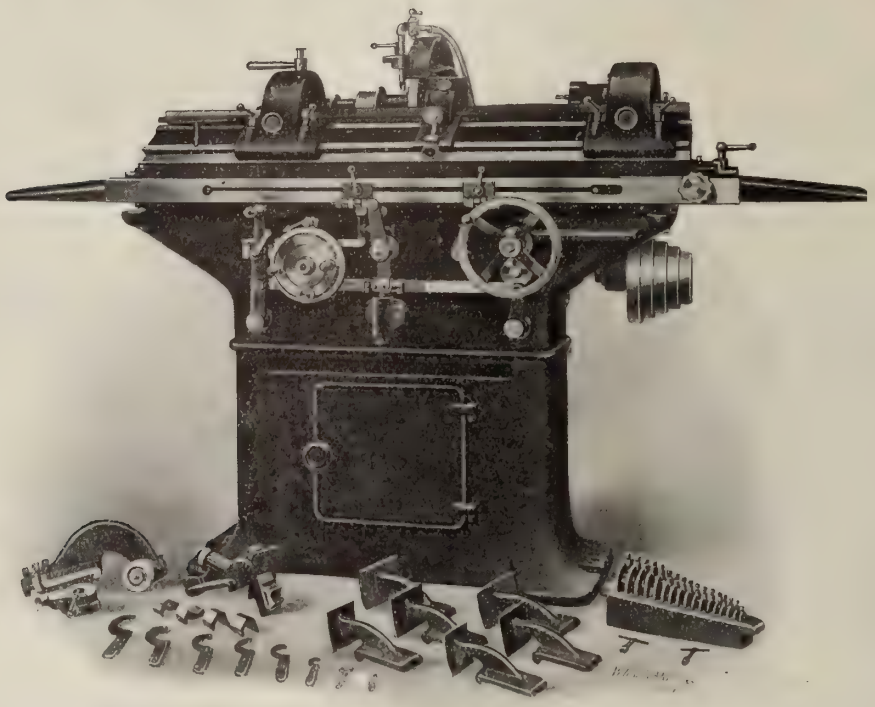
C.P. Railway, Montreal, Toronto, Winnipeg; G. T. Railway, Point St. Charles; Canadian Westinghouse Company; Dominion Steel Company; Nova Scotia Steel Company; Montreal Rolling Mills; Canadian Rand Company.

WRITE FOR INFORMATION TO

ACETYLENE CONSTRUCTION CO., Limited

604 POWER BUILDING, MONTREAL, P.Q.

"MORSE"



PLAIN AND UNIVERSAL GRINDING MACHINES

incorporate many desirable improvements, the advantages of which are emphatically demonstrated by their use. Built rigidly, they run with minimum vibration; will size work automatically to .00025 inch, the cross feed being absolutely reliable. Spindles protected from water and emery; travel of table is automatic. On the Universal, traverse speed instantly changed from a roughing to a finishing speed.

Send for illustrated circulars.

Morse Twist Drill & Machine Co.

New Bedford, Mass.

CANADIAN MACHINERY BUYERS' DIRECTORY

To Our Readers—Use this directory when seeking to buy any machinery or power equipment. You will often get information that will save you money.

To Our Advertisers—Send in your name for insertion under the heading of the lines you make or sell.

To Non-Advertisers—A nominal rate of $1 per line a year is charged non-advertisers.

THE WORLD'S DRILLING RECORDS

made with "Cleveland" High Speed Drills, announced in recent issues of the representative mechanical journals, can't have escaped you. Perhaps you consider these remarkable results impracticable in your own shop because of the carefully regulated ideal conditions under which the tests were made—but

A PRACTICAL TEST OF CLEVELAND Drills

under your own shop conditions will demonstrate to you what results can be obtained from scientifically made drills in every-day service.

Your investment in a trial order of "Cleveland" High Speed Drills will pay you dividends in the form of increased production and reduced cost, which mean *larger profits.*

Don't overlook this opportunity to increase the drilling efficiency of **your** shop. Immediately upon request, we will send you Folder No. 32-C.

"W & B" Wrenches Meet Every Need

From Flying Machine To Submarine

We Supply The World's Wrenches

"W&B" Diamond Trade Marked Wrenches can be found in every branch of industry in every quarter of the Globe. Whatever your requirements are, there's a **"W&B" Wrench** to fill them.

We are in touch with the world's progress in invention and processes of manufacture. This is why you can call for a **"W&B" Wrench** to fill your individual need.

Our wide range of styles and sizes include the necessary strength and finish for the work to be performed.

A modern plant with every kind of cost reducing equipment enables us to quote the lowest prices for such high quality wrenches.

Your nearest jobber can supply you or you can send order direct.

Write for Catalogs 74-C and 75-C.

TRADE W B CO TOOLS OF QUALITY BEAR THESE MARKS W&B MARKS

The **"W&B" Diamond Trade Marks** offer absolute protection to the buyer and user of wrenches, and other high grade **"W&B"** Tools. . *Right materials, efficient service* and the *greatest economy* are always found wherever the **"W&B" Diamonds** are located.

Hardening a Cutter is the only process in its manufacture that does not depend upon mechanical means for its success.

The first steps in the manufacture of accurate cutters—turning the blank, boring, cutting the teeth, etc.—are dependent upon accurate mechanical means. The same is true of the last step—sharpening.

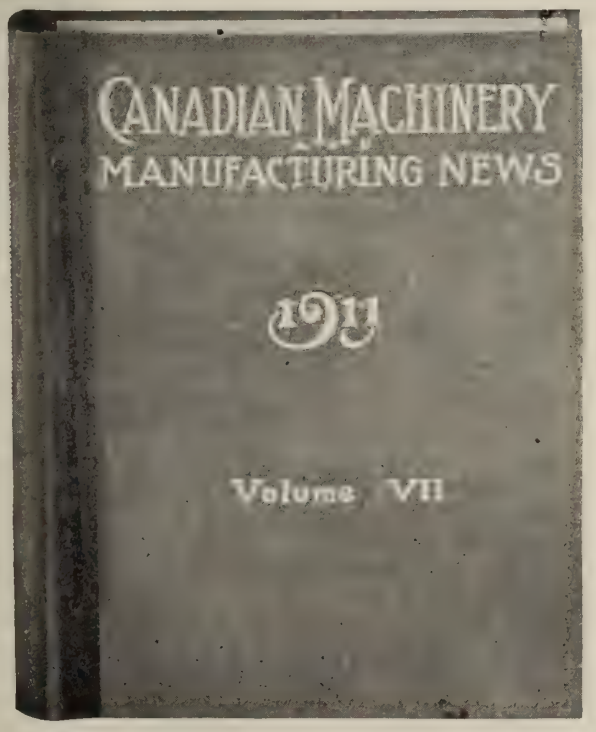
When it comes to hardening, the very opposite is true. No mechanical means have been found that will successfully perform the work—all depends upon the skill of the workmen and their experience.

Our men are highly skilled and have the experience of more than half a century of hardening to back them.

Shall we send our Cutter List?

BROWN & SHARPE MFG. CO.

PROVIDENCE, R.I., U.S.A.



The Technical Papers of To-day

ARE THE

Textbooks of To-morrow

¶ **Therefore,** Be in advance of the times by binding your copies of Canadian Machinery. To help you do this and, in addition, assist you in keeping them clean and easy of access for reference, we will send Canadian Machinery for one year and a "Common Tie" Binder for $1.50, or to present subscribers we will furnish the binder at 50c. each post paid.

¶ A complete alphabetical index for 1911 is now being prepared and will be mailed to subscribers in a few days.

Steel Castings

Joliette Steel & Iron Foundry, Ltd.---Main Works Building

We make new process converter steel castings, annealed and unannealed.

We also make Chrome Manganese and Nickel Steel Castings.

All sizes, ¼ lb. to 30,000 lbs.

WRITE TO US.

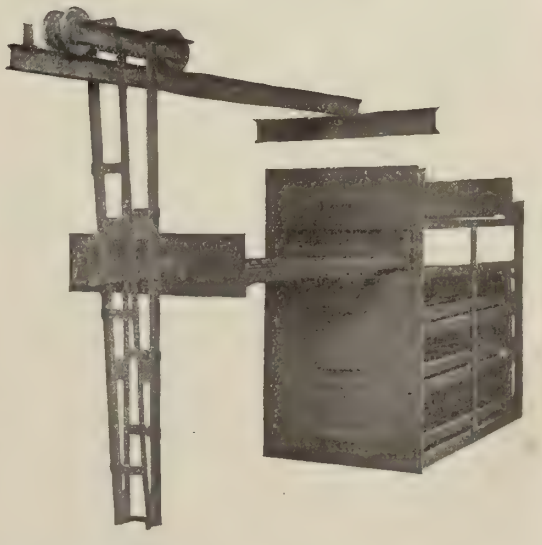
PROMPT SHIPMENTS



This is something that every foundryman wants when he orders his goods.
We are prepared to give you service, quality, and lowest prices on anything from a DUST BAG to a CUPOLA. If you are not using EUREKA BLACKING you ought to. It's the BEST on the MARKET.
EUREKA CORE COMPOUND (a pitch core compound) of 100% purity, mixes much the same as flour and is as readily taken from the castings. Will not blow and is cheaper than flour.
No. 48 PLUMBAGO, a high graphitic carbon lead, will do the best kind of work, if you are looking for that kind. Write for latest catalog of Polishers' and Platers' Supplies.

THE McDougall Lathe is strong and solid at the gap, with remarkable refinement of tool control. It saves adjustment time. Factory efficiency and quality of product demand its use.

DESCRIPTION.

Headstock construction prevents chattering, and deep oil chambers fitted with ring oilers make spindles and bearings self-oiling and always well lubricated.

Tailstock of a special type, and sleeve is clamped by a quick acting locking device. Tailstock is secured to bed by bolts adjusted from the top where they are easily accessible.

Bed, non-springing and webbed, and braced to secure rigidity.

Gap, vibration absolutely prevented by use of brace supports to carriage.

Spindle, high carbon hammered steel in solid chilled cast iron bearings, accurately fitted and self oiling.

Carriage and Apron, non-springing under severest strain, full "V" bearings and flat bearings in addition on front ways.

Double Back Gears give eighteen distinct spindle speeds, suiting lathe to work on widely different diameters.

Compound Rest, with graduated base, accurately fitted taper gibs, end adjusted. Screws in both rest and cross slide read to thousandths.

Friction, Safety Feeds, screw and rod feeds cannot be both engaged at the same time. Quick changes of 1¼, 2½ and 5 times thread being cut.

Gears and Racks, cut from solid and steel where necessary.

Screw Cutting, full range of commercial threads provided tor

Equipment, Compound rest, steady rest, follow rest, large and small face plates, wrenches, two-speed, friction countershaft furnished with each lathe.

Accuracy, Strength, Solidity, Wear. These are the paramount features behind all McDougall Machines. Made **to meet extreme demands.**

ANY UNSKILLED MECHANIC CAN PRODUCE PRECISION SCREWS on the

Pratt & Whitney Thread Miller

Screws within very narrow limits of error can now be produced on a commercial basis. No longer do you require high-grade engine lathes and high-class mechanics. This heretofore difficult and expensive operation performed with greater accuracy and in less time by cheap labor.

Process is automatic and one man can operate six machines.

Write for full descriptive catalog "Thread Millers."

A PERFECT SURFACE

A MIRROR FINISH IN BUT ONE OPERATION.

The Pratt & Whitney VERTICAL Surface Grinder

reduces any metal, rough or finished, hard or soft, to a flat surface that will not vary .0002". Moreover, it accomplishes this at a great saving over former planing and milling methods. Pratt & Whitney Co. will furnish estimates as to production and capacity and will also grind samples.

ADJUSTABLE "S"

Nut Wrench

Ideal for Particular Work

A mechanic who has a very particular job to handle should use a wrench that is best suited for the work—a wrench that grips firmly when used in inconvenient corners—a wrench that will not destroy the work by slipping.

"B. & C." Adjustable "S" Nut Wrenches are very strong and durable, having an operating nut of steel, and a sliding jaw of steel drop forging.

They are hardened and tempered under our own supervision, and guaranteed right both in quality and price. All parts interchangeable.

Cost Reducing Features

An indestructible spindle bearing made of hardened steel and cast iron.

A head construction that gives more effective pulling power at the spindle than any other lathe built.

A patent "compensating V" that permits four times the bearing area between the carriage and bed found on other lathes.

A carriage in which the tool thrust is taken on a bearing the entire length of the carriage, and which positively will not climb the V.

A double-walled one-piece apron which will last as long as the rest of the lathe.

A quick change gear complete in one unit, giving thirty-six changes with two operating levers.

An offset compound rest which can be used without skinning the operator's knuckles.

The centres set back of the middle of the bed, giving greater swing over carriage and permitting the turning of work up to the maximum swing without the tool overhanging the bed.

Garvin Screw Machines

GIVE UNSURPASSED SATISFACTION

The best materials are used in manufacturing these machines. Parts made of Krupp Chrome Nickel Steel, Drop Steel Forgings and Vanadium Steel Springs. Absolutely no steel castings used. Machines can be realigned under all conditions of wear. Spindles are of large diameter, bearings are ground and run in bronze boxes. Cross-slides fitted with plug stops, capable of fine adjustment, and can be lifted from bed without removing turret base. Hexagon Turrets on all machines, except the No. 1. Independent stops to each of the six turret holes. Our turrets and slides have long been renowned for their rigidity without cumbersomeness, the result being large output. The turret momentum is stopped by a solid plug, the lock bolt being used for indexing only. Many other exclusive features.

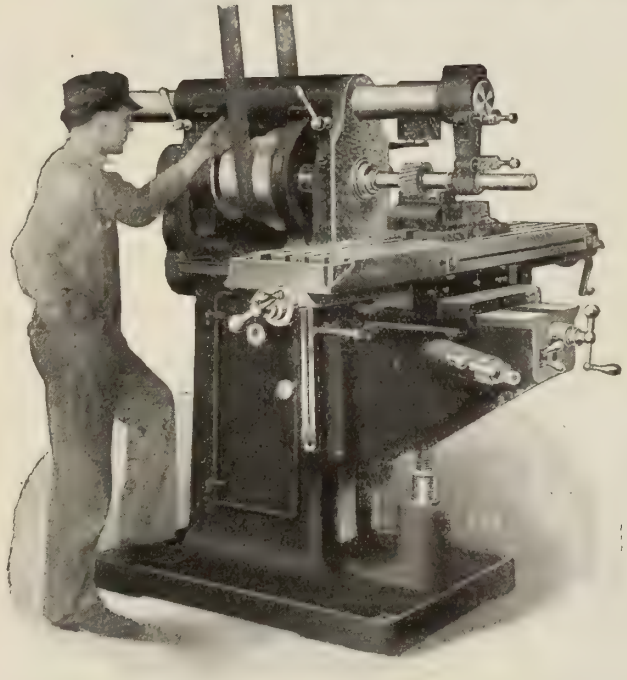
LeBLOND MILLERS



CONVENIENCE OF OPERATION

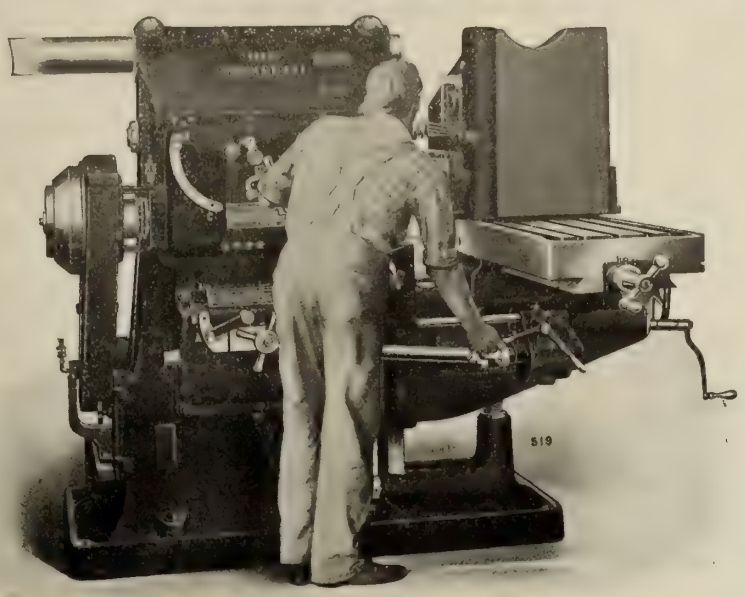
ON manufacturing operations it is not often necessary to shift the cone belt as the ***Double Friction Back Gears*** give the operator a roughing and finishing speed by merely shifting a lever. But when he does find it necessary he can do so without danger and without the use of a stick or a club, as our back gears are on the right hand side, the left hand side being clear of all obstructions, such as gear guards and revolving back gear quill.

The R. K. LeBlond Machine Tool Co., Cincinnati, Ohio

Canadian Agents—GENERAL SUPPLY CO , Ottawa, Toronto and Winnipeg.

The advertiser would like to know where you saw his advertisement—tell him.

Cincinnati Handiness



WHEN you have a job of end or face milling to do on a Horizontal Miller, don't you find it hard to operate the feed lever and at the same time keep your eye on the cutter? That's because the machines you are using can be operated from only one place. Our new High Power Machines have an additional feed lever at the side of the knee.

The operator can stand close up to his work, with the cutter in full view, and control the machine from this position.

With this one lever he can operate and reverse table, cross or vertical feeds.

The main starting lever is immediately in front of him and the speed and feed changes are at his elbow, so that the entire machine is under complete control from here.

Save On The Single Piece As Well As The Big Job

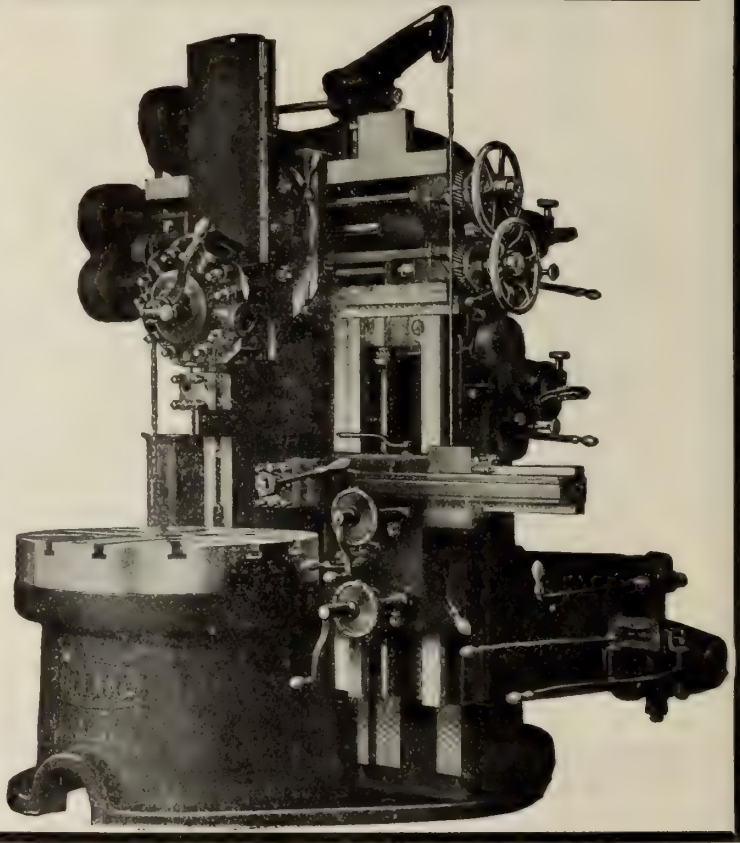
The Bullard Vertical Turret Lathe is not alone a manufacturing machine—the very features which make it a good manufacturing machine also reduce the cost of the individual piece.

The Vertical Turret Lathe is ready to save on face plate work of every description within its capacity. Vertical Construction, Ample Power and Rigidity, Multi-Cutting, Quick Speed Change, Centralized Control, Automatic Lubrication—these cost-reducing factors save on the single piece as well as on the big job. It does not keep the foreman on the jump looking for the right job. Nor does it require an expensive special tool equipment for each job.

Investigate. Find out how much less YOUR face plate work will cost done on a Vertical Turret Lathe.

We'll be glad to put some interesting facts and figures before you.

Send for Treatise on Face Plate Work, No. C-15, NOW.



The Bullard Machine Tool Co.

BRIDGEPORT, CONN., U.S.A.

The advertiser would like to know where you saw his advertisement—tell him.

You Can Double Your Output If You Install a

"SPRINGFIELD" Cabinet Turret Lathe

This is one of our latest productions and it contains several new features and improvements that ensure a maximum output at minimum cost. Its accuracy, speed and efficiency cannot be equalled.

The turret is so designed that one slight backward movement of the blades loosens the turret and at the same time withdraws the locking pin; a slight forward movement then produces the partial revolution of the turret for the next tool, and simultaneously locks and tightens it, the entire operation being done in a second or so by one hand.

This lathe is back geared, and has a four-step cone pulley of large diameter.

Do not hesitate. Write us at once for illustrated catalogue on our complete line of lathes and shapers. "SPRINGFIELD SERVICE" is guaranteed to save you money.

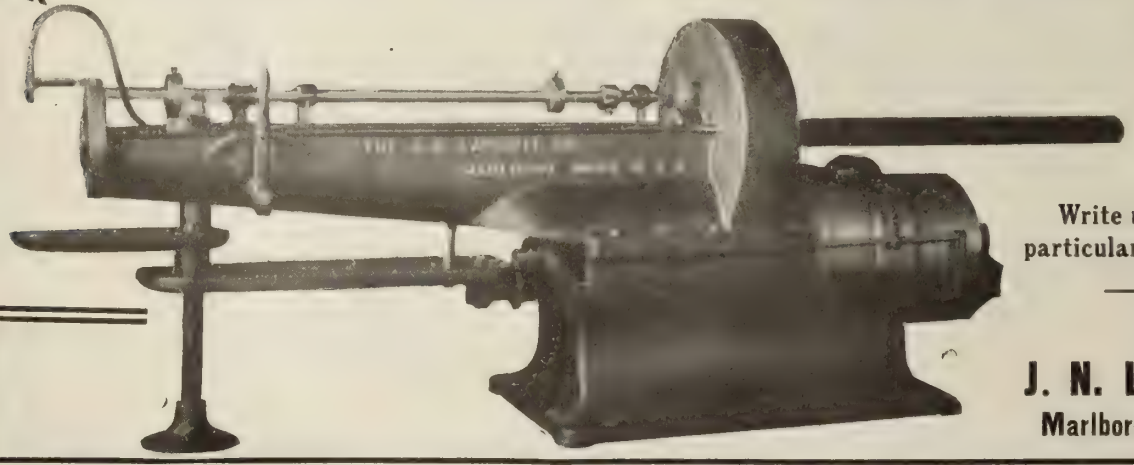
Factory and Main Office: NEW BRITAIN, CONN.

An IMPROVED BROACHING MACHINE

That will be of Great Value to YOUR Shop

It has several improvements over many machines of this type and is capable of doing from the smallest to the heaviest broaching practicable. The construction of this machine is such that friction is reduced to the minimum amount, which gives at least 30 per cent. more pulling capacity than machines with the same power applied. The driving gears of this Broaching Machine are encased, running in grease, which eliminates considerable time in oiling.

As there are no pins or positive clutch in the driving, but simply belts shifting on tight and loose pulleys, the machine can be run at any speed desired without being exposed to injury. The Improved Broaching Machine is provided with an automatic oil pump, flooding the work with oil while being broached, and is also furnished with countershaft complete.

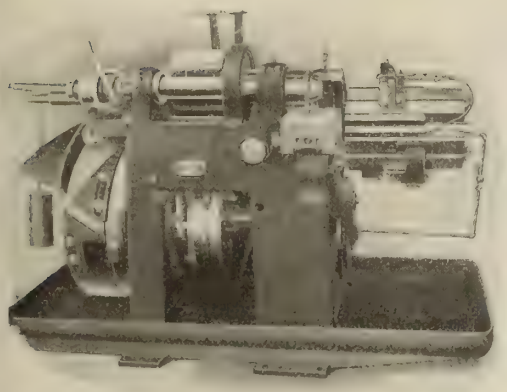


It increases quality and quantity of work.

Write us at once for full particulars, if interested.

The
J. N. Lapointe Co.
Marlboro, Mass., U.S.A.

Speed - Convenience - Economy



"GRIDLEY" SINGLE SPINDLE

These are three of the essential features that are combined with absolute accuracy.

"Gridley" Automatic TURRET LATHE

This Lathe will greatly increase your output, and will handle work of greater length and of more complex character than any other machine of this type.

One operator can attend to several machines at once, and can use tools tandem, thereby increasing production and at a minimum labor cost.

If you do not already know this Lathe it will pay you to investigate. Let us send you a list of well-known firms who are using it. Write them and get their verdict.

Every minute means money to you--drop us a card at once.

We manufacture both Multiple Spindle and Single Spindle Automatics.

IT PAYS TO FIGURE COSTS

Do You Drill Holes ? How Many ?

How much does the labor cost in a year's time ?
How many hands on that kind of work ?

The *Avey*

Ball Bearing Drilling Machine runs at speeds varying from 2 to 4½ times the speeds of ordinary drills, according to size of hole.

The Saving is Proportionate

Figure out for yourself what this would do in your own shop and then ask yourself:

Does the Old Machine Pay ?

You are paying for a new one—why not get it ?

Ask us for further information.

The New Geared Feed

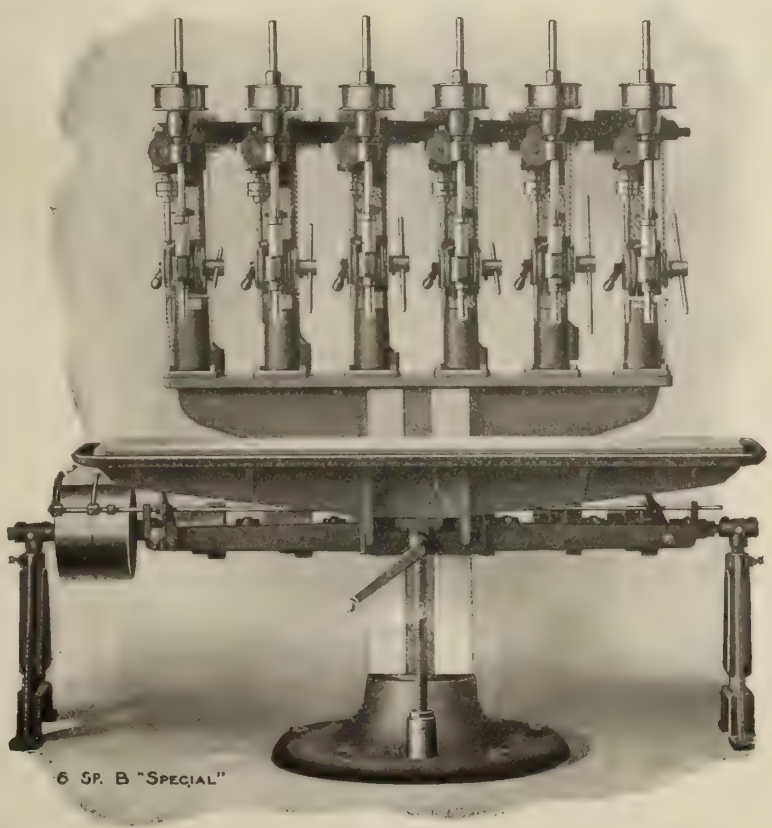
ON OUR

SLIDING HEAD DRILLS

has enabled us to *double* our output on one or two jobs—and on others has given a remarkable increase in efficiency over the belt feed formerly used.

Sibley Machine Tool Co.

Church Lane **South Bend, Ind., U.S.A.**



HARD CASTINGS

The illustration shows a six spindle Style "B" multiple spindle "BARR" Drilling Machine, fitted with the "BARR" Slip Friction, for use in drilling castings that are liable to come hard.

Three distinct results are obtained by the use of the "Slip Friction."

1. **Does away with inspection of castings.**
2. **Saves breaking of twist drills.**
3. **Saves the machine itself.**

Our Style "B" is power feed automatic stop and quick return. Combined with this slip friction, the output is enormous. This style of machine with the frictions is now in use in one of the largest factories making agricultural implements in Canada.

Economy—Reliability—Efficiency

BLOUNT'S
Wet Tool Grinder

This machine is the outcome of necessity, and is the result of hard study and years of experimenting with the aim to produce a tool grinder of superior quality.

So little power is required that the grinder can be run continuously at practically no cost.

Filled with self-oiling bearings, so that there is no wear of parts, as the propeller of the pump, furnishing a constant supply of water, is loosely fitted, and does not touch the case at the nearest point. A sleeve cap prevents leakage without the use of packing

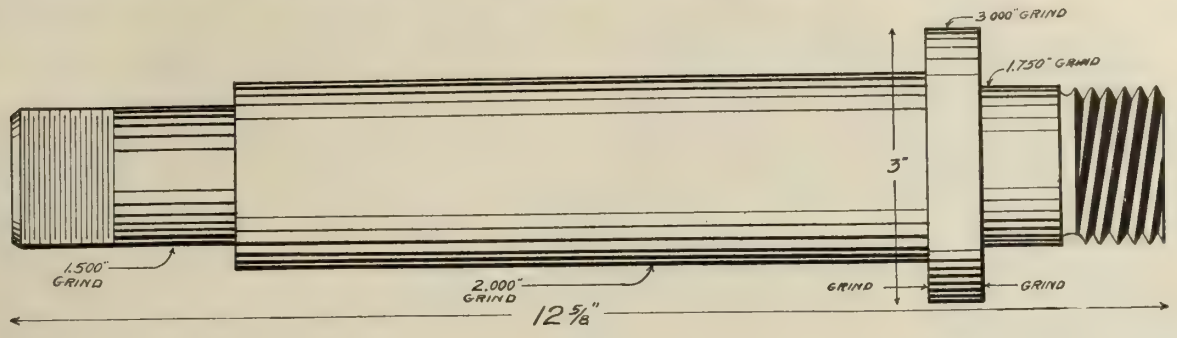
Here's a convincing story—

Shows just what Real Grinding Efficiency is, on

THE BATH GRINDER



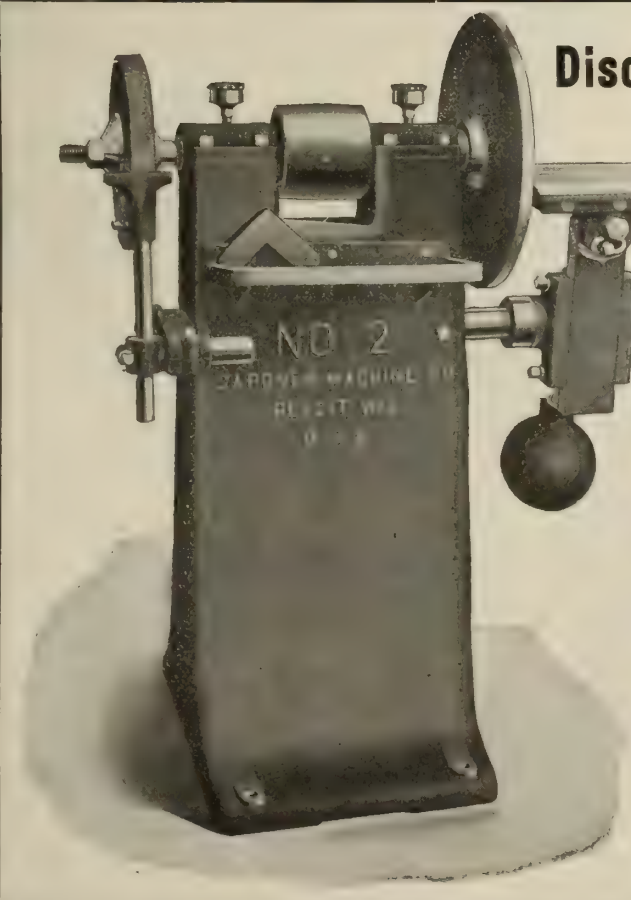
Study these figures with your own products in mind.

The above piece of work is hardened tool steel, stock removed .030″ off all diameters, limit of variation allowed .00025″.

Ground to a high finish in addition to the grinding of the four diameters. Shoulders are face ground—and the average time for each piece is only 15 minutes.

Let us send you our latest Catalogue.

THE BATH GRINDER COMPANY, Fitchburg, Mass., U.S.A.



Disc Grinder for "All-Around" Work

Gardner No. 2, with Emery Wheel Attachment.

Here is a combination of a Disc Wheel and a Solid Abrasive Wheel, which makes one of the most convenient, economical and practical machine tools to be found. The Lever Feed Table in connection with the Disc Wheel adds greatly to the accuracy and speed at which work can be done. Various types of tables and work rests can be furnished.

ITS USES.

While this machine is very useful in all general shop operations, it appeals most strongly to the smaller manufacturers, the tool room, foundries operating machine shops, and polishing departments.

An ideal equipment would be as follows: Universal Lever Feed Table in right hand end, Work Stand on left hand end, 2--18" diameter Disc Wheels with an assortment of Abrasive Discs, 2 Solid Abrasive Wheels, a Gardner Band Polishing Wheel and an assortment of Polishing Bands, Wheel Press, Countershaft, Cement, etc.

Get circular and prices for immediate delivery.

GARDNER LITERATURE YOU NEED !

We issue catalogues and booklets completely covering the largest and most reliable line of Disc Grinding machinery and Accessories on the market. Do you know what a 4000 ton stock of Tool Steel means?

It means having good steel, or it could not be sold fast enough to net a profit. We are not in business for charity.

It means possessing the confidence of a sufficient number of customers who will help shift this enormous stock—and that quickly.

It means that our steel is making good, or we would not dare to keep stock up to the 4000 ton mark.

It means that our steel is shifting fast—mighty fast.

Why shouldn't it! Our claims are true. Our steel is good. Our prices right.

"SISCO ACORN" IS OUR STEEL.

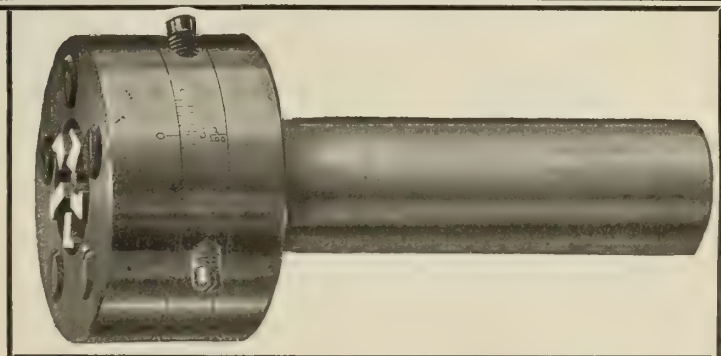
Geometric Adjustable Hollow Milling Tool

The Only Practical Hollow Milling Tool On The Market.



Especially designed for Brass Finishing. Most serviceable and economical for reducing duplicate parts to an exact diameter prior to threading. Can also be used for light cutting on cast iron, steel or similar material. Not recommended, however, in place of roughing or finishing box tools for general screw machine work.

Extremely simple and durable. Easily adjusted. The cutters project beyond the face of the cam so as to permit of milling right up to a shoulder, where necessary.

We are prepared to furnish various styles of Geometric Adjustable Hollow Milling Tools, as well as special tools of this class to meet special working conditions.

Our Standard Hollow Milling Tools are furnished in sizes from 7/16″ to 4″ inclusive. Send us a sample or correct blue print of the work you wish to do, and we will submit quotations promptly.

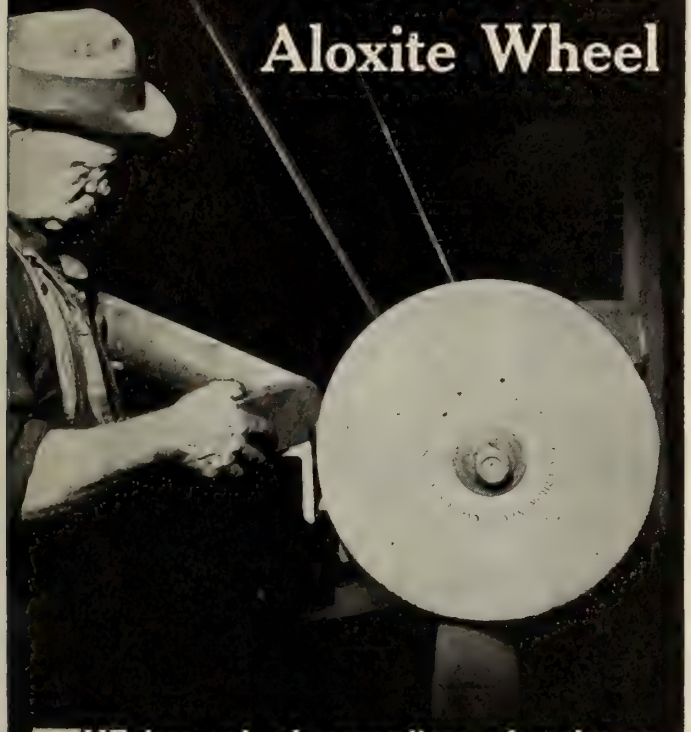
Grinding Steel Dredge Pins with an Aloxite Wheel



THE best wheel, regardless of make or price, that a Hoboken, N. J., plant ever had for this class of work is an Aloxite, 18-inch wheel. The pins were two feet long, 5 inches in diameter, made from 45 point carbon steel and were ground just as they came from the steam hammer—every pin was ground smooth and clean—the wheel cut fast and free and stood up so well that there was no chance for comparison with the wheels formerly used.

It is again the logic of having the right wheel in the right place—let us help you increase production and decrease cost in your grinding department.

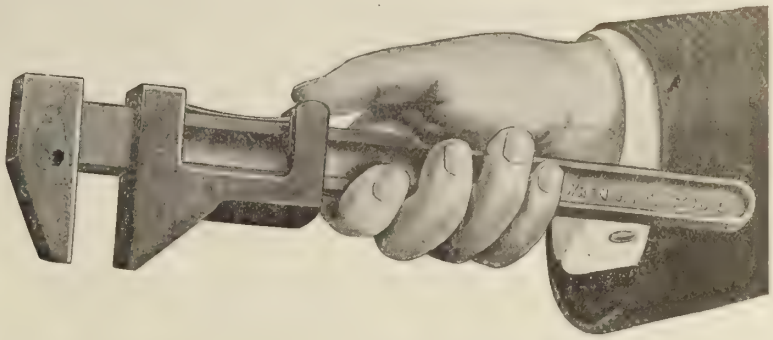
The
WRIGHT WRENCH
Certainly is the
RIGHT WRENCH



Simple, strong, practical, and a wonderful time saver. Instantly adjusted to any sized nut by simply pressing with the thumb. Can be adjusted and used with one hand.

The adjustment is constant—IT STAYS PUT. No spring or back-lash as in screw wrenches—never slips or locks on a nut. Does more work in less time than any other wrench.

Used and endorsed by the Baldwin Locomotive Works, by master mechanics of several railroads, of a United States Navy Yard and of the Bell Telephone Co., and by hundreds of construction companies and machinists.

Made in 6, 8, 10, 12, 15 and 18-inch sizes, and in Automobile pattern in 8 and 10-inch sizes.

Sample 10-inch wrench sent postpaid to any point in Canada on receipt of $1.00. All sizes kept in stock.

METALLIC CONTACT

When a bearing is not lubricated, or the oil film has broken down and the shaft rests directly upon the bearing, they are in metallic contact.

It is a common occurrence for the weight of the shaft to squeeze out the oil film over night, and when the Engine is started up, heating and abrasion take place before the trouble is discovered. An ordinary bearing metal can be used successfully if kept thoroughly lubricated, but as this is difficult, unless the lubrication is forced, it is neither safe nor economical to use such metals. We recently published a letter showing that Magnolia Metal had been running on a motor drive head shaft for sixteen years, and for six years of that period it had not received a drop of lubrication. We also recently published a letter showing 50% saving in oil, because the engineer had been able to use his oil over and over again "until it was all used up" and everybody knows that filtered oils lose their lubricating qualities. We also published test made by the United States Government using **water** as a lubricant.

These letters and test, and many others, of similar character, go to show that Magnolia is largely independent of lubrication, and therefore is not liable to injury from scant or inferior lubrication and stands up where other bearing metals go down. The use of Magnolia will end your bearing troubles.

SPECIAL OFFER

PRACTICAL ENGINEER POCKET BOOK. 680 pages, over 2000 subjects. Price 40c. post paid. We do not aim to make a profit on these books. We buy them in large quantities as an advertising medium and give Engineers benefit of low price. They are highly spoken of by Engineers. Address Montreal office.

Two Great Needs Filled

Goodyear Sheet Packing for High or Low Pressure
Magnet High-Pressure Gasket Tubing

After months of painstaking experiment we have perfected Sheet Packing and high-pressure *Gasket Tubing* that forever *do away* with the disappointment, trouble and expense caused consumers by the many cheap and worthless grades that have been placed on the market.

Magnet Sheet Packing

Made of the celebrated Magnet compound, this packing is totally ***unaffected by heat, oil, liquor (ammonia), alkali, or by expansion or contraction.***

It is suitable for high or low pressure uses, particularly high, because of its heat-resisting properties. It neither becomes hard nor brittle. Retains its tough, elastic efficiency for months.

Magnet Sheet Packing won't *blow out.* It makes a tight joint that stays tight under air, hot or cold water or strain pressure.

Meets every requirement.

No engine room, locomotive, steamboat or machine shop is properly equipped without a roll of this great emergency packing.

GOODYEAR

Magnet High-Pressure Gasket Tubing

Made also from the celebrated Magnet Compound. Forms a tight joint no matter how rough the surface may be—and it is

Pressure-Proof

Magnet Gasket Tubing can't blow out. Like Magnet Sheeting, it successfuly resists any degree of steam heat and it maintains its elasticity.

Cut to Fit

One of the big advantages of Magnet Gasket Tubing is that it may be cut any length to fit any size manhole or handhole, plate or pipe flange. Cut ends joined together with rubber core, making *continuous gasket.* Put up in convenient boxes with rubber core and tape.

If you need sheet packing or gasket tubing, grasp this opportunity. The Goodyear trade-mark stands for reduced first cost and economy all along the line. It stands for the same quality workmanship that underlies the success of the Goodyear Tire & Rubber Company, Akron, Ohio, one of the best known and most experienced manufacturers of rubber goods in the world. In all of our business in Canada last year, we had to replace, because of slight defects, only $155.22 worth of goods.

RENOLD PATENT SILENT CHAINS

What Users Think

Montreal, Feb. 8, 1909

Messrs. Jones & Glassco, Montreal

RE RENOLD SILENT CHAIN DRIVE.

GENTLEMEN,—In reply to your inquiry of Jan. 30th, I may say that the Renold Silent Chain Drives we have installed are giving every satisfaction.

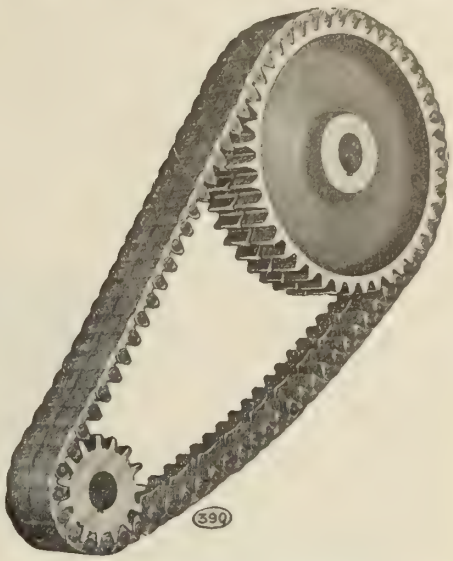
Our first drive was installed to replace a 12 in. belt which was giving us trouble on account of short centres: this chain has run continuously for four years without the slightest trouble.

Our second drive was installed on a mixing machine doing heavy duty and which had previously broken up two sets of spur gearing, this chain has run over three years with no sign of wear yet.

Our third drive was installed on a calendering machine after breaking two sets of helical gears, and this has been so successful that we are now installing two more similar drives.

I would be perfectly willing to make an appointment with any person genuinely interested and show him the drive in operation.

The above comes from one of the largest manufacturers in Montreal and is signed by the Mechanical Superintendent. Up to the present (1911) these drives have not received repairs of any kind.



Write for Catalogue

So satisfactory has their experience been that they are ordering (for a new extension) Renold Chain Drives throughout.

PUMPS

The superior excellence and splendid results shown by

"FAIRBANKS-MORSE"

pumping machinery are largely due to the fact that for many years we have manufactured Hydraulic Machinery of all descriptions. We are therefore able to build pumps which are properly designed and adapted to every-day use. This is of the greatest importance in a first-class pump, for the usefulness of an engine may be lost if the pumping machine is badly designed.

You will get all these important features when you purchase a "FAIRBANKS-MORSE" pump.

Let us solve your pump problems.

Illustrated Description of the Johnson Stock Gang

The Writer of this Article, Who by the Way is also the Designer of the Machine, Shows the Successful Outcome of a Complete Departure from Standard Practice, in Layout and Detail of this Important Accessory of the Saw Mill and Lumber Industry. Needless to Say, the Complete Mechanism is at Once a Tribute to Canadian Genius and Constructional Ability.

UNUSUALLY HEAVY STOCK GANG OF NEW DESIGN.

By Geo. H. Johnson.

DURING the season of 1909, the writer received instructions to develop a machine that would increase the output and improve the quality of the cut in our No. 3 mill. It was somewhat reluctantly decided to build a heavy machine of untried design, and only after having investigated the record and performance of all the standard stock gangs of Canadian, American and Swedish design; because none of these machines were suited to our needs.

Some of the conditions the new machine would have to fill were very exacting:—

(1)—An output of 225 thousand feet in 10 hours when cutting two by twelve white pine.

(2)—Feed necessary to obtain above output not to exceed 9-16 inch per revolution.

(3)—No oak or timber of any kind to be used in foundation or machine design.

(4)—Machine to be rigidly rock bolted and placed on solid concrete.

(5)—Revolutions per minute not to exceed 260 in order to assure necessary output.

Outstanding Features.

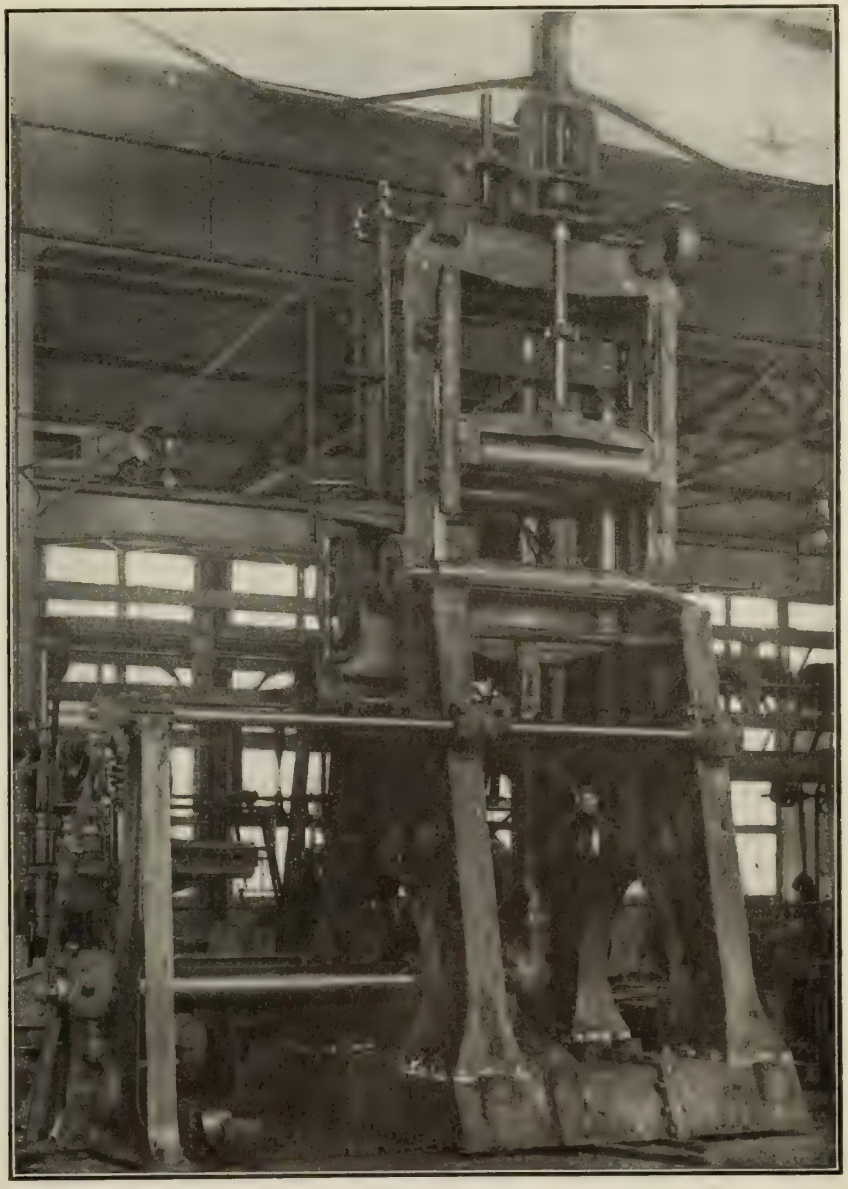
Any designer of heavy mill machinery will recognize that some of the above conditions were radical. First, the usual practice in all heavy stock gangs is to place about 2 feet of oak timbers between top of concrete pier and bottom of machine to serve the purpose of a cushion to the extremely heavy stresses generated in the crank shaft by the heavy unbalanced loads running vertical at high speeds. The writer can recall instances where the best 10 and 12-inch steel shafts procurable failed after being but a few months in service; one of the largest firms on the Ottawa River, making it a practice to replace all stock gang crank shafts after 12 months' service, whether these showed defects or not.

It was finally decided to ask the John Inglis Co., of Toronto, to assist in developing a machine to meet our requirements, they agreeing to put a machine together to suit us, but not being held liable for faulty design or performance; the firm of McLachlin Brothers, Ltd., Arnprior, being alone responsible for the success or failure of the complete mechanism.

Figure 1 gives a somewhat clear idea of the new machine when finished and standing in the shops in Toronto. This new Stock Gang, running nearly to 100 tons in weight, is we believe the heaviest machine attempted up to present time, and some of the details of the design will probably be of interest.

Details of Design.

The illustration shows crank shaft stripped. When ready for work, this shaft carries a heavy 48 inch dia. by 48 inch face pulley with double web construction instead of the usual arms, also two 3-ton fly wheels about 6 ft. dia., one of the latter being mounted on crank disc. Having been proved on other machines of this type that an 8 inch crank pin shrunk into a steel disc would only stay tight a few months, it was decided to machine pin and disc out of the solid—this is quite clearly



The Johnson Stock Gang in the Erecting Shop of the John Inglis Co., Toronto.

shown in the photographs. The mounting of the frames on top of the main bearing casting has proved to be successful in every way; the usual practice being to cast the main bearings separate in order to overcome the tendency to transmit crank shaft vibrations through the A frames.

All bearings carry heavy steel shells, water jacketed and arranged for forced grease lubrication. It will probably be of interest to mention that a genuine babbit will not run under these machines. The metal used must have a lead base. The oscillation of the sash which is the critical element of all stock gangs has proved highly successful and permits of a 24 inch cut with a 20 inch stroke. The lumber in the yard rarely shows the feed marks. All guides are water jacketed and arrang-

ed for forced-feed oil lubricant. Metal of any kind will not run on these guides, but an arrangement of end lignum vitae with brass centre will run indefinitely with very little wear. The crank pins are water jacketed and arranged for forced-feed grease as shown in Fig. 3.

The oil is fed to the centre hole, a packing nut being provided. The two outer tubes are for the water supply, inward and outward flow. In the illustration, 1 is a brass crank arm; 2, a brass collar; 3, a brass sleeve; 4, a brass nut; 5, a brass nut; 6, a brass ring; 7, wrought iron set screw; 8, wrought iron oil pipes and 9, tap bolts. Steel castings and forgings are used freely throughout the design; the sash and lower girt being of special selected material. Screw press rolls were

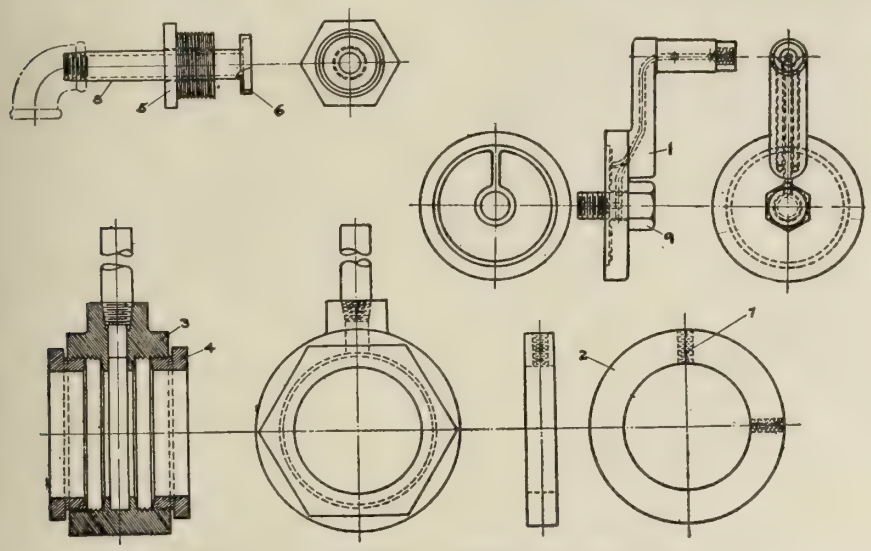

Fig. 3.—Crank Pin Lubricating Device on Johnson Gang Press.

used on the machine shown, but steam binders were fitted to two other gangs developed at the same time, and designed to handle the small stocks.

It will probably interest vertical engine designers and engineers, who are accustomed to gently easing a crank pin over the centre by nicely adjusted lead and cylinder compression, to state that these machines with a heavy crank pin load of some tons running at 260 rev. per minute, can be made to run as cool and smoothly as a quiet running engine. The performance of the machine illustrated and the two small machines not shown has been peculiarly consistent and successful in every way. After a season's run with an output of approx. 70 million feet of pine, the stoppage clerk's reports fail to show a stop of any of the above mentioned machines of longer duration than 20 minutes during a 10 hour working day. This we believe is a record, and may disprove the idea usually held that a large saw mill is somewhat loosely run, instead of the highly specialized business it has become of late years.

In conclusion I would like to record my appreciation of the genial co-operation of the The John Inglis Co. especially Mr. Printz and Mr. Ward of the draughting office, to whom much of the success of the machines described is due.

RAILWAY AND CANAL EXPENDITURE IN CANADA.

The annual report of the Department of Railways and Canals shows a total expenditure by the department during the year of no less than $40,180,326, of which $36,301,979 was on railways. The main items of capital expenditure included $23,488,208 on the National Transcontinental, $184,149 on the Hudson Bay Railway, and $227,563 for the Quebec bridge. It is interesting to note that the total Government expenditure on railways in Canada now amounts to the enormous total of $475,489,401, while on canals the total expenditure has been $130,200,470, making a grand total expenditure of $606,000,000. On the other side of the account there has been a total revenue from Government railways of $157,406,587, and from the canals of $14,377,392. On the National Transcontinental Railway the capital expenditure last year was $55,293,999. During the fiscal year the total payments of the railway subsidies were $1,284,892.

The main figures with regard to the operation of government railways last year show gross earnings of $10,249,394, with a net profit of $211,515. The Intercolonial Railway working expenses were $9,595,976, with earnings of $9,863,783, a profit of $267,806. It is pointed out, however, that an additional amount of $200,000 was taken out of revenue at the end of the year and placed to the credit of the fund for renewals. If this extra amount for renewals had not been so taken the net profit for the year would have been nearly half a million. The deficit on the Prince Edward Island Railway was $86,684, and on the Windsor branch $30,693.

The total traffic through the canals in 1910-11 was 42,990,608 tons of freight and 320,574 passengers, an increase in each case. On the Welland Canal 2,326,290 tons of freight were moved, of which Canadian vessels carried two-thirds, and the quantity of grain carried through the Welland and St. Lawrence canals was 485,499 tons, an increase of 40,080 tons over the previous year. On the Sault Ste. Marie Canal 36,395,687 tons of freight were moved, and the passage of 7,972 vessels was recorded. Of wheat, 68,396,300 bushels were transported.

THE CANADIAN TUBE & IRON CO.

The demand for rivets, bolts, and nuts has increased steadily during the last three years, but during that period no new companies entered the field to meet it, until recently, when the Canadian Tube and Iron Co. was formed. With the advent of the new year, the bolt factory started producing, and from it there is now being amassed a stock of various lines. The head office and works are in Montreal on the Lachine canal. This latter water-way gives excellent shipping facilities, the coal, raw material, and finished product being handled by an electric crane, one runway serving both the barges and siding which connects with all the railways.

The bolt and nut plant of the new company comprises four buildings, a wire mill, forge shop, threading floor, and a warehouse; the four buildings covering an area of 60,000 sq. feet and having producing capacity equal to the largest mills in Canada. The machinery installed is all of the latest and most approved type, having been imported from various U.S. manufacturers within the last four months. The lines made include rivets, bolts, nuts and coach screws. For heavy nuts and bolts there is the usual equipment of crude oil furnaces and stamping machines. The smaller lines are punched cold. There is also a pipe mill producing butt-weld pipe of all sizes up to and including 4 inches. For galvanizing, the hot process is used, there being the usual tanks for surphuric and hydrocholoric acids and spelter.

The executive of the Canadian Tube & Iron Company is as follows:—

Pres.—J. W. McConnell.

Vice-pres. and man. dir.—J. L. Waldie.

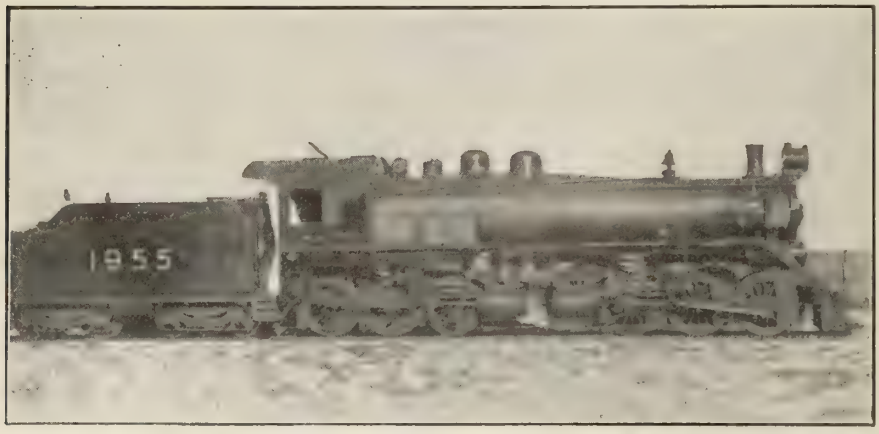
Sec.-treas.—H Worrall.

Sales man. and dir.—A. H. Hough.

Directors.—W Mosley, W. Molson McPherson, H. A. Lovett, Dr. Hersey.

THE LATEST MALLET LOCOMOTIVE ON THE C. P. R.

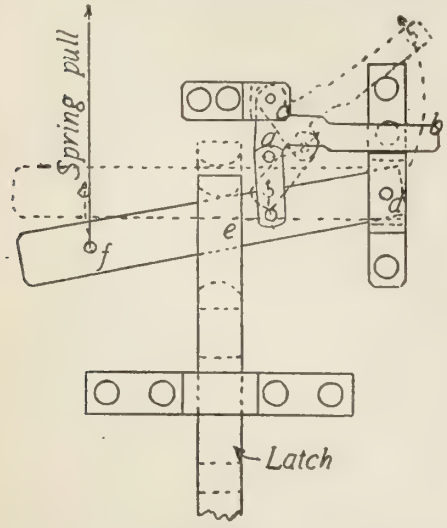
OUR illustration shows Engine 1955, the latest Mallet articulated locomotive turned out from the Angus Shops, Montreal. As announced in our issue of last October, it differs from previous Mallet engines built by the C. P. R. in being a non-compound and is the only engine of her class in America, if we except a much larger one



Non-compound Mallet Locomotive, C. P. R.

built last fall by the Pennsylvania Railroad. The latter, however, has an entirely different wheel arrangement, being of the 2-8-8-2 type.

The four cylinders of Engine 1955 are 20 inches diameter by 26 inches stroke, each taking steam direct from the boiler. Distribution is by piston valves operated by Walschaert valve gear. Power reverse gear is provided and may be operated by either steam



SKETCH B.
Portion of Steamshovel Dipper Door Showing Arrangement of Spring Latch.
(a) Toggle Joint. (b) Power to break Joint. (c) Fulcrum of toggle lever. (d) Fulcrum of spring lever. (e) Weight of latch. (f) Power of spring.

or air, the latter being the medium ordinarily employed. As may be seen from the illustration, the locomotive is of the 0-6-6-0 type, and has the cylinders back to back, this arrangement having been adopted on all the Mallet engines so far built by the Canadian Pacific Railway Co. The wheels are 58 inches diameter and the boiler pressure 200 pounds per square inch, which gives a tractive force at the rails of approximately 56,000 pounds. The total wheel base is 35 feet 2 inches, and the weight of the engine in working order is 262,000 pounds, all of which is of course available for adhesion. The tender is the same as that used with the M4 class of Consolidation engines, and has a capacity of 12 tons of coal and 5,000 Imperial gallons of water; its loaded weight being 133,000 pounds.

Boiler Particulars.

To provide steam to four high pressure cylinders, the boiler of No. 1955 is of course larger than those on sister engines, which are compound. It is fitted with standard Vaughan-Horsey superheater and has the following general dimensions:—

	Inches.
Outside dia (front course).....	65¼
Outside dia (behind taper course)	74½
Distance between tube sheets 20 ft.	0⅜
Number of tubes:	
24—5¼ inches dia.	
167—2¼ inches dia.	
18—2 inches dia.	
Total..	209

		Sq. Feet.
Heating Surface.....	Tubes	2,764
	Firebox	185
	Superheater	548
	Total..	3,497

Grate Area 59

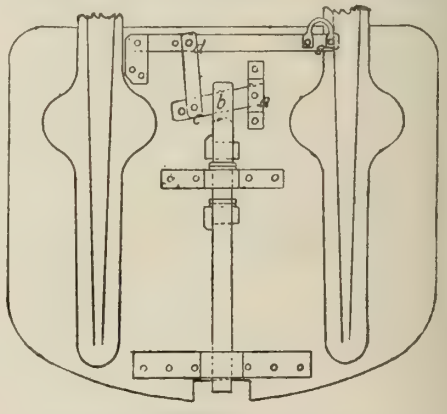
The board seen on the side of the smoke box, near the front, carries a water gauge for measuring the vacuum caused by the blast. This gauge is not a permanent fixture, being placed there for experimental purposes only. At the time of writing, the engine is undergoing a series of tests between North Bay and Chalk River, upon satisfactory completion of which, she will be put into freight or pusher service on the British Clumbia division.

STEAMSHOVEL DIPPER TRIPS.

AN investigation is under way at the Panama Canal to determine the relative efficiency of the steamshovel "trips," operated by steam, known as the Geddes and Wichman "trips." These are a culmination of a development in the improvement of tripping devices that began soon after the first steamshovels were set at work in Culebra Cut.

Suitable Unlatching Device the Aim.

In the accompanying sketch C, the dipper of the shovel is shown in dumping position, the emptying process being accomplished by pulling a latch, by which the door of the shovel is held. When the shovel is ready to dig, the dipper is near the ground with its centre back of a vertical line through the centre of the shipper shaft, as the shaft of the big gear is called. In this position, the door of the dipper closes of its own weight and is latched firmly. When the dipper is loaded, the spoil within it bears down upon the door and tends to hold it so firmly in place that the power required to open the latch is often so great as to cause a serious strain on the craneman, who unlatches the door. Ease in opening the door is an advantage, both to the craneman and in accelerating the work of digging. The various improvements on methods of unlatching, or of "tripping" the latch, as it is called, have in view this dual advantage.



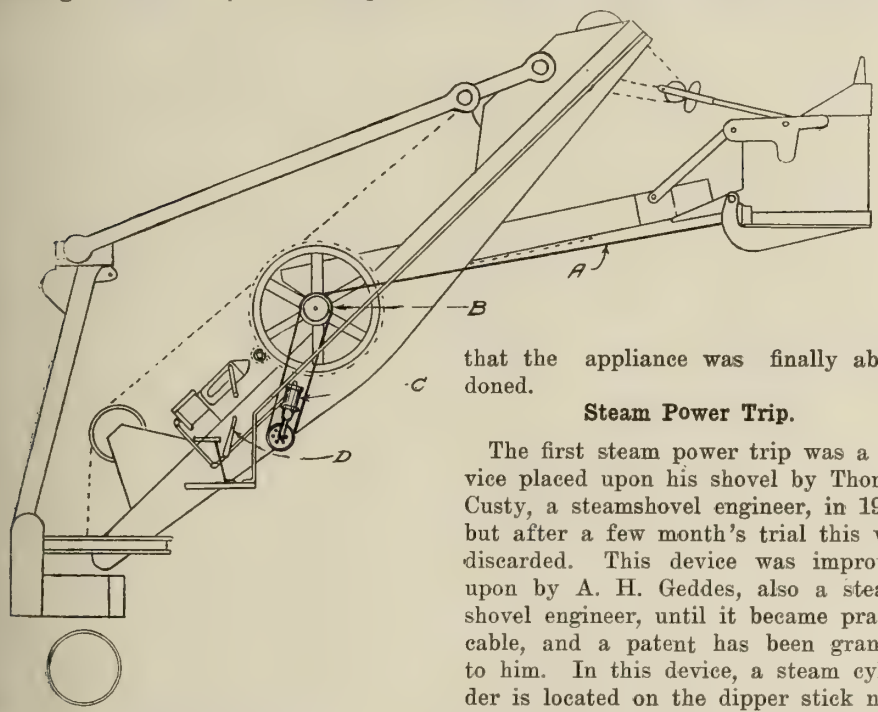
SKETCH A.
Door of Dipper of 95 ton Steam Shovel Showing Compound Latch Trip.
Height of Door ..... 4¾ feet
Width ..... 5½ feet

When the shovels arrived on the Isthmus they were equipped with a single lever latch operated by a 1¼-inch rope in the hand of the craneman, and attached at its other end to the

"trip" of the dipper. Several pulls were often necessary to open the latch, and almost invariably a great effort was required. The string by which this "trip" was operated passed through a sheave on the dipper stick near the dipper and thence to the craneman's hand.

Unlatching Improvements Devised.

The first improvement was to compound this original "trip," and in the drawing herewith A, the compound



SKETCH C.
Steamshovel Boom, showing Dipper Stick, Dipper, and Operating Gear, with Wichman Tripping Device.
A—½-inch Wire Rope. B—Winding Drum. C—Steam Cylinders. D.—Operating Lever.

"trip" is shown. The original was the simple lever with the fulcrum at (a), the weight at (b) and the power at (c). In the compound "trip," another fulcrum was made at (d) and the power was applied at (e), where the line was attached. By this device a movement of 20 inches in the line resulted in a 1-inch movement of the latch.

Among improvements upon the compound device, one that was given a trial in 1909 was the "spring trip" which consisted of the lever, shown in the second illustration herewith, B, and a bar passing through a slot in the latch, with a spring attached at its outer end; the power for unlatching being supplied by the spring. The rope by which the "trip" is operated is attached at (b), the fulcrums are at (c) and (d), at (a) is a toggle joint, at (e) the weight and at (f) the power applied by the spring. The door is closed by its own weight, when in digging position, placing a tension of 1,300 pounds upon the spring, and drawing the toggle joint erect. When the dipper is in the dumping position, the craneman pulls the rope, thereby breaking the toggle joint and allowing the spring to exert its pull upon the latch, which flies back, permitting the dipper to empty. The spring required was of ½-inch wire, 31 coils, 2¼ inches outside diameter, and 21 inches long when free. This device worked satisfactorily, but the toggle joint required constant renewing, and some difficulty was experienced in obtaining suitable springs, so that the appliance was finally abandoned.

Steam Power Trip.

The first steam power trip was a device placed upon his shovel by Thomas Custy, a steamshovel engineer, in 1908, but after a few month's trial this was discarded. This device was improved upon by A. H. Geddes, also a steamshovel engineer, until it became practicable, and a patent has been granted to him. In this device, a steam cylinder is located on the dipper stick near the dipper, the piston is connected with the dipper latch through a chain and a series of levers, and when steam is admitted to the cylinder, the thrust of the piston operates the levers and unlatches the door. Steam is admitted and exhausted from the cylinder through a three-way valve located on the boom beside the craneman's seat. A steam pipe extends from the valve along the boom opposite the dipper stick slot, and at the end of this pipe and on the cylinder, are universal joints which are connected with one another by a flexible hose. After a thorough trial this device was adopted, upon the recommendation of a committee of two mechanical experts and a steamshovel engineer, who reported that the capacity of a shovel was increased 100 cubic yards a day by its use.

A Further Improvement.

The latest device, that shown in the illustration, was invented by F. S. Wichman of the Mechanical Division. The latch is opened by a pull made on a ½-inch wire rope by the outward thrust of the piston of an air brake cylinder. The mechanism is fixed upon the boom of the shovel. A drum is mounted upon the face of the thrusting gear, or shipper shaft, which revolves with the shaft, thus winding or unwinding the tripper rope, according as the dipper shaft moves up or down. In this way the rope is kept taut at all times. To give the lengthwise pull of the cable, a 6-inch diameter steam cylinder is mounted below the drum. This cylinder has a push piston, the outer end of which is bifurcated to receive a sheave, over which the cable passes on its way to the drum. Steam is admitted to the cylinder, when it is desired to trip the dipper door, through a three-way cock, operated by a lever at the craneman's seat. When the steam exhausts, the spring in the cylinder pulls the piston back into position, and the tripping operation may then be repeated. This device has undergone a successful test on two 95-ton steamshovels.—Canal Record.

FINANCES OF THE DOMINION OF CANADA.

The statement, indicating the condition of the finances of the Dominion of Canada at the end of December last, which has just been issued by the Finance Department, shows that during that month the public debt decreased $2,049,980, as compared with $878,661 during the same month of 1910. The net debt amounted on December 31 to $313,386,651, as against $315,436,632 on November 30, and $326,885,959 on December 31, 1910. The gross debt at the close of the year was $478,488,871, as compared with $477,587,701 a year before.

The statement announced that the revenues of December totalled $11,596,099, and the revenues for the nine months ending December 31 totalled $99,482,947. The figures for December, 1910, and for the first nine months of that year were $9,790,387 and $85,665,833, respectively. Expenditures on consolidated fund were in December last $6,519,861, and during the nine months' period $54,303,871. The figures in 1910 were for December $5,355,286, and for the nine months $52,994,133. Capital expenditures amounted in December, 1911, to $3,148,159, and in the nine months ending December 31 to $18,983,354. The capital expenditures in December, 1910, totalled $3,680,305, and in the nine months ending December 31 of that year $22,804,247.

LARGE LOCOMOTIVE CONTRACT.

The Montreal Locomotive Works, Ltd., have recently received from the Canadian Pacific Ry., an order for 75 ten-wheel engines of the D.10 class, having cylinders 21 inches diameter by

28 inches stroke and 63-inch wheels. The boiler has a total heating surface of 2,420 square feet, and is fitted with the Vaughan-Horsey superheater. The steam pipes from superheater to cylinders will be located outside the smoke-box, in accordance with the most recent practice on the C.P.R. The engines weigh about 190,000 pounds in working order, exclusive of the tender. Delivery is to commence in May and be completed in August.

This substantial contract will doubtless give employment to a full staff at the Montreal Locomotive Works.

THE DOMINION BRIDGE CO.

The Dominion Bridge Company is going to locate a large western plant at Calgary. This has been decided by the board of directors. The Calgary plant will be bigger than that at Winnipeg. The western business has grown to such an extent as to make a plant in the west a necessity.

The board of directors had almost decided to triple the size of the Winnipeg shops, which at present employ between 300 and 400 men, but on considering the matter further, they arranged to look Calgary over, as the greater bulk of their western business lay beyond Winnipeg. A short time ago, J. K. L. Ross, a director and son of James Ross, the chief shareholder of the company, went to Calgary, and having studied the location and conditions, thought it would be more profitable to build a plant there, and reported to the board of directors accordingly.

INDUSTRIAL EDUCATION IN LONDON, ONT.

By Thames.

FEW movements have been so characteristic of the economic and social conditions of the age in which they occurred as the Industrial Education movement. It has been a direct result of changed modern industrial conditions. The specialization in the large industries of to-day has resulted in reducing the workman in many cases, to a mere operative with little or no knowledge of the processes which precede and follow the one which he, day in and day out, performs. The apprenticeship system has well nigh passed away; it is, therefore, little to be wondered at that thoughtful men the world over are agreed that some means must be devised to supply to the rising generation of workers the training which modern conditions require of the successful artizan, but which no longer can be obtained in the shops.

Germany was the first country to attack the problem, and it is still from that country that much of the inspiration and guidance along industrial education lines may be drawn. England, France and Switzerland followed in her wake, and now the movement has spread to America. Canada naturally did not feel the pressure of the charge so soon as the older countries where competition was more keen, but the problem of industrial education is now a question of national movement with us.

The city of London, Ont., happens to be a leader in this advanced educational movement. Mr. E. R. Dennis, the head of one of the large iron industries there has long been an advocate of the cause. He established classes for his own employes to demonstrate what might be done along this line, and was a candidate for the school board, making industrial education the issue. So impressed were the electors, that Mr. Dennis was given the largest vote ever polled in a school trustee election in that city. The Board have now established a general evening industrial school which has no equal in Canada, and were fortunate in securing in Mr. H. B. Beal as principal, a gentleman who was thoroughly posted on the industrial education movement in other countries, and in addition possessing exceptional executive ability, was well acquainted with the local requirements.

What impresses one most in discussing the question with Mr. Beal is the definiteness of the aim which he has in view and the clearness with which he states it. He knows just what the school aims to do, and is quite as free to tell you what it does not attempt to accomplish. One of the factors which has sown doubt as to the success of the movement generally, in some quarters, is the lack of definiteness of aim of its advocates. This is certainly not the case in London. The London industrial school has three main courses for men and boys, viz.:—Machine Shop Practice, Woodworking and Forge Shop Work. Each student selecting one of these courses must take with it a course in drawing and must also devote a short period to English. This feature, of insuring that each student who takes a shop course will also gain an acquaintance with the making and use of mechanical drawings and blue prints and will possess a sufficient knowledge of English to express himself intelligently, is one of the unique features of the London school.

The women and girls receive instructions in dress-making, sewing, cooking and home economics from instructors who fill the responsible positions in city establishments at their respective lines of work. The women and girls also take a course in practical English.

That London has approached this practical problem in a thoroughly practical manner may be judged from the fact that the instructors in every department are those who have been a success in the same line of work in local industries. She is not following the mistake that so many other places have made in attempting to give an academic solution to an intensely practical problem. Any of our readers, who may be passing through, will do well to take an evening off and visit the London Industrial School. They will find a first class equipment, an energetic and enthusiastic lot of teachers and a class of pupils who tax the classes to their utmost capacity.

UNSAFE RAILS ON U. S. RAILWAYS

James A. Farrell, president of the United States Steel Corporation, in his evidence before the Stanley Steel Investigating Committee, threw much light on various phases of the steel business. He testified that most of the rails used by the great railroads of America, are of an inferior grade; that the lines placed economy before safety, and that such rails would not be tolerated in Great Britain.

As to the use of inferior rails, Mr. Farrell said that virtually all the American systems demand rails containing a large proportion of carbon, because they are more economical than soft steel rails. He told the committee that while rails with a high proportion of carbon, gave in many instances long and excellent service, they were liable to become brittle, crack and cause wrecks. Reports made by the chief inspector of safety appliances of the Interstate Commerce Commission, he continued, state that many wrecks were caused by rails cracking or separating, which conditions were superinduced by "pipes" in the steel. These "pipes" were caused by too much carbon in the steel.

The rails used, according to his testimony, are cheaper than those used in any of the great European countries, notwithstanding the fact that they are forced to bear greater loads, under more trying conditions, than are imposed upon the rails of Europe.

A locomotive of 1,000 h.p. driven by a Diesel engine, has just been set to work on the Prussian State Railways. The drive is direct to the axles, and the outward appearance is similar to that of an electric locomotive. Nearly $60,000 have been spent in experimenting with this engine.

Oil Burning Locomotives on the Tehuantepec N.R.R. Mexico*

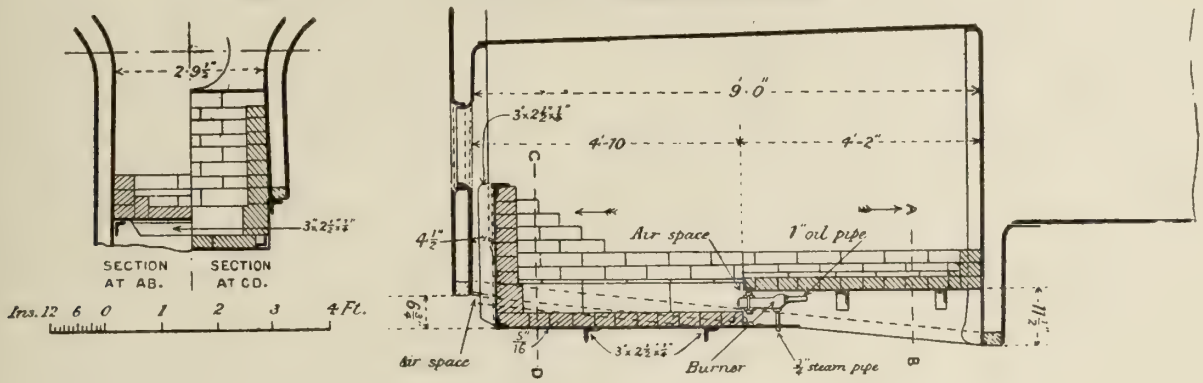
By R. Godfrey Aston**

The Question of Oil Fuel for Steam Boilers is a Particularly Live One at the Present Time, and in View of the Fact That Our Great Railroads Have Under Consideration the Adoption of Oil Fuel in Their Locomotives, the Information and Data Furnished by the Writer of this Paper Becomes Particularly Opportune and Valuable to the Many Readers of this Journal in Railroad Shops, etc.

THE object of this paper is to give an account of liquid-fuel burning in the locomotives of the Tehuantepec National Railway, showing some of its advantages over coal, and giving a general description of facilities for handling and storing this fuel-oil, the methods of burning it, and a few results gained which are taken from the monthly performance of locomotives. The author does not intend to deal fully with costs, etc., as it is too large a subject for so short a paper, but will confine himself to a more practical point of view.

Tehuantepec National Railway.

Fig. 1.—Front End Oil-Fuel Burner Arranged in Locomotive Firebox.



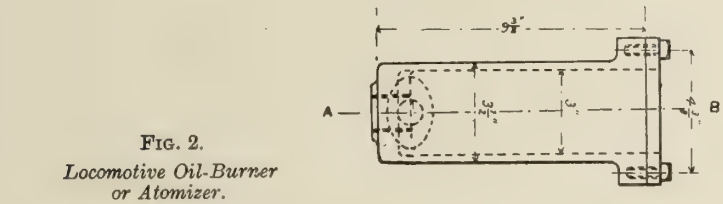


FIG. 2.
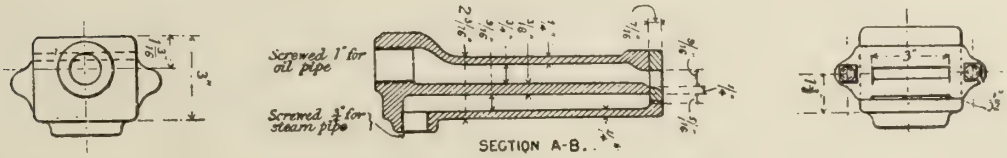
Locomotive Oil-Burner or Atomizer.

Made by the Company.



The Tehuantepec Railway is a transcontinental line of standard gauge, 4 feet 8½ inches, 189 miles long, running across the Mexican Isthmus of Tehuantepec from the port of Puerto, Mexico (Coatzacoalcos) on the Atlantic, to the port of Salina Cruz on the Pacific, with grades varying from level to 2.15 per cent., and abounding in curves up to 11 degs. 28 mins. radius, and where the speed of trains is limited to 15 miles per hour.

Storage Facilities.

All fuel-oil for the company is received at the terminal of Puerto Mexico, where the main storage-tanks are situated; these comprise three cylindrical steel tanks, each composed of six tiers of steel plates riveted together and a light steel roof, with three manholes, and a ventilator in the middle through which gases arising from the oil can escape. Two of these tanks are 95 feet diameter and also used for giving oil to engines, etc. 37 feet 6 inches deep, each with a capacity of 46,996 barrels of 42 United States gallons (35 British gallons). The third tank is 92 feet diameter and 29 feet 9 inches deep and has a capacity of 35,138 U.S. barrels.

These tanks are all enclosed in separate earthen embankments, and are connected together by an 8-inch pipe-line, which enters the tanks 18 inches from the bottom; this space being required for water, settling out of the oil, etc., and which can be drawn off through a 3-inch valve at the bottom of the tank. The pipe-line runs down to the wharf, where it is fitted with an 8-inch check-valve, and it is from here that vessels delivering cargoes of oil can pump straight into any tank, the two largest tanks being about 1¼ miles from the wharf. At convenient places in the pipe-line, near to the round-house, are stand-columns for filling engine-tanks, tank-cars, etc., and near the round-house is also a supply tank of 28,000 U. S. gallons capacity, erected upon a structural steel frame,

The terminal of Salina Cruz is laid out in the same manner, except that there are only two storage-tanks, 95 feet diameter and 37 feet 6 inches deep, of 46,996 barrels capacity. The capacity of all these storage-tanks has been calculated out in U.S. barrels of 42 gallons for every 6 inches of depth, allowance being made for all internal stays, supports, etc. The fuel-oil is shipped from Puerto Mexico to the other fuel-stations in specially constructed double-truck steel-frame tank-cars of 6,600 U.S. gal-

*Paper read before the Institution of Mechanical Engineers, London, England, December, 1911.

**Graduate Institution of Mechanical Engineers, Rincon Antonio, Oax., Mexico.

lons capacity, the gallons per inch of depth of these cars being known, so that the exact amount contained in each car can be credited to the station to which it is shipped.

Fuel Oil.

The fuel-oil used is purchased from the Texas Company of Port Arthur, Texas, at about 97½ cents gold, per barrel of 42 U.S. gallons delivered at Puerto Mexico, and pumped into the Railway Company's tanks by the delivering vessel. This fuel-oil is generally delivered in tank-steamers, and sometimes towing barges, which come right up alongside the Railway Company's wharf. The coupling between the vessel and the company's land pipe-line is made with a flexible rubber or steel hose, which is supplied by the vessel.

This fuel-oil is quite thin, and flows readily through pipes of any diameter; it is sometimes nearly black in color, and sometimes a dark brown with a green fluorescence. The Railway Company stipulates in its contracts with the Texas Company that the flash-point (closed) shall not be under 110° F., as a lower flash-point than this is liable to be dangerous on account of the volatile gases and fumes which arise from the oil at comparatively low temperatures. The author has seen the oil catch fire from a torch which was some 10 or 12 feet away from it. Some oils may be used in the crude state as fuel, while others have to be passed through the refinery. After the lighter oils, etc., have been taken off, the by-product or residuum is used in a satisfactory manner as fuel, and as such has been and is used in Mexico. Fuel-oil contains no power of spontaneous combustion, and unlike coal does not deteriorate if stored in tanks or reservoirs.

The specific gravity of this oil varies from 0.790 to about 0.942, and its weight per U.S. gallon from 6.4 to 7.75 lb. The British Thermal Units vary from 17,000 to 20,000, the average being from 19,500 to 19,800, and between this and the best steam-coal there is a very great difference. The analysis of two samples of the oil as used by this company for fuel is as follows:—

Specific Gravity @ 60° F.	0.931	0.881
Baume Gravity @ 60° F.	20.5°	29°
Flash-Point (closed)	130° F.	135° F.
Flash-Point (open)	160° F.	160° F.
Fire Test	220° F.	224° F.
Setting Point	3° F.	20° F.
Viscosity @ 100° F.	200 seconds (Redwood)	78 seconds (Redwood)
Sulphur	0.77 per cent.	0.26 per cent.
Calorific Value	10,688 calories	11,000 calories
Color	Dark brown	Dark brown
Water and Dirt	1 per cent.	0.25 per cent.

The standard temperature for the measurement of fuel-oil is 60° F., and expansion is allowed for at the rate of 1 per cent. for every 20° F. increase in temperature above 60° F., and contraction at the same rate for decrease in temperature below 60° F.

Locomotives.

The locomotives in use on this road are of the Baldwin consolidation type, the main dimensions of which are:

Cylinders—20 inches by 26 inches.

Wheels (drivers)—53 inches diameter on tread.

Fire-box—Length inside, 108 inches; width inside, 33½ inches.

Flues—239 of 2 inches outside diameter.

Grate area—24.94 square feet.

Heating surface—Fire-box, 147; flues, 1,700. Total, 1,847 square feet.

Boiler pressure—170 lbs. per square inch.

The oil-tank is fitted into the coal space of the tender, and its contents calculated for every half-inch of depth. Most oil-tanks have a capacity of 2,000 gallons, and the oil is fed from the tank to the burner or atomizer through suitable connections and flexible brass ball-joints.

Fire Box Arrangement.

The company's practice, after trying various types of burners and atomizers, is to use what is called a front-end burner, Fig. 1, that is, the burner mouth points towards the back of the fire-box, or fire-box door-plate. The burner is placed in a 9-foot fire-box, 4 feet 2 inches from the flue-sheet, the flame playing against a brick wall built up to the level of the fire-box door opening. Between this brick wall and the fire-box back-plate is a 4-inch air-space extending the whole width of the fire-box and right up to the top of the brick wall. Brick walls are built up on each side of the fire-box from the height of the brick wall at the back, gradually sloping downwards; the floor of the grate or ash-pan is laid all over with fire-brick. No brick arch or baffle plate is used.

As mentioned in the preceding paragraph, the burner is placed 4 feet 2 inches from the flue sheet, and midway between the sides of the fire-box, so that both in front and behind the burner or atomizer there is a flat bricked-over area of fire-grate; and as the burner is placed parallel to the lower grate, there is a 4-inch space between the front and back grates, this 4-inch space being left open to admit air, extending from one side of the fire-box to the other.

Brickwork.

This should be of the very best material and workmanship, as it is subject to a much greater heat than from a coal fire; if this is not done, the walls will not stand, and engine failures will occur; moreover, the failure of only one brick will perhaps necessitate new brickwork throughout, thus needlessly running up expenses. There is no reason why the brickwork should not stand from four to six months, and perhaps longer, if due care be taken from the start. A good brick should contain about 80 to 85 per cent. of silica and from 20 to 15 per cent. of alumina, and should be as free as possible from alkalies, which cause fluxing. A good brick becomes surface-glazed though remaining rough and porous. It should be perfectly dry when built up in a fire-box, otherwise the heat will cause it to crack. If possible, the fire-bricks should be fired at a temperature as high as that to which they will be exposed when in use.

Burner or Atomizer

There are many and various kinds of hydro-carbon burners, and after a trial of various types, including the "Baldwin" and "Best" burners, this company is using with considerable success a burner which is made in their own shops, and which is really an inverted "Best" burner, Fig. 2. It is a simple device which allows the oil to fall from an orifice 3 inches wide by 9-16-inch deep over the top of a flat steam-jet 3 inches wide and 1-32-inch deep, the steam picking up the oil and sending it into the fire-box in the form of a spray. The underneath jet of steam delivers the spray of oil at an angle, so that it strikes the brick wall in the middle, instead of shooting out from the burner parallel with the bottom of the ash-pan. This burner may be called an outside atomizer, and although it is in general use it has its drawbacks; but it has been found to be more efficient than any other they have used.

The most essential points about a burner or atomizer are:

(1) Its atomizing capacity. All fuel-oil is heavy, and will burn in the form of a vapor or spray only when mixed with air. The object should be to fill the fire-box with a soft and voluminous flame, and not to impinge it in any one place.

(2) Its facility for keeping clean and free from clogging.

(3) Its adjustability in giving the right direction to the flame or spray, and regulating the proper proportion of oil and the agent, either steam or air, used for atomizing.

A burner that will vaporize or atomize the oil at the point of expansion of the agent used for that purpose, which is easily handled, and will atomize the greatest amount of fuel with the least possible energy, is the highest and most efficient that can be designed. On this

railway, steam is used as the atomizing agent, because, after various experiments, it was found to be superior to air. The steam to a very great extent heats the oil as it flows into the burner before delivery in the form of a vapor spray. The flame from the burner should not be too long or it will pass into the flues and become extinguished. Gases which are only partly consumed will relight in the smoke-box.

Lighting-up an Oil Burning Engine.

In each round-house of this company is a stationary boiler, always in steam, used for the washout and other pumps, as well as for lighting up dead engines. From this boiler is laid a 2-inch steam line to points between each engine road or stall. From there a connection can be made to a locomotive through a 3-way cock, or T piece in the steam-pipe leading from the steam stand on top of the fire-box to the burner. By use of this steam the burner can be started and kept going until the boiler has generated enough steam to keep the burner going itself. A piece of oily waste is lighted and thrown into the fire-box just in front of the burner from which the spray ignites. Connections can be made to any other engine all ready in steam should the stationary boiler not be available for any reason.

Firing and Cleaning Flues on the Road.

With an oil-burning engine there is always a fire of equal intensity and one which never gets dirty, so that good steaming is practically ensured. It is a popular idea that it is a very easy matter to fire an oil-burning engine, but this is not the case, as both skill and care are required, so that the author thinks it best to lay down a few of the most important rules:

(1) See that the oil-tank is full, and if heaters are used, that they are in operation, and that the temperature of the oil is as it should be.

(2) See that the sand-box on the foot-plate is full, and that the scoop is in its place.

(3) Before starting the fire, see if the temperature of the fire-box is below igniting point, which is a dull red, and if so, open dampers (if used), start the blower, and open the atomizer-valve fairly hard; then put a piece of saturated oily waste on the bottom of the grate after setting it alight, close the dampers (if used) and fire-box door, and turn on the oil very light. When the oil has ignited, reduce the blower and atomizer to a light feed, also the oil until the chimney is quite clear of smoke.

(4) See that the fire is burning brightly, and that there is no oil on the bottom of the pan, also that the brickwork is in good condition, and that no bricks or any other obstructions are on the bottom of the grate or pan so as to obstruct the flame or jet on its way from the burner to the brick wall.

(5) As regards cleaning flues on the road, it is best to sand frequently if the engine is being worked hard, say every 9 or 12½ miles, but if the engine is being worked light, every 31 or 37 mile will be sufficient.

(6) Having attained a fair rate of speed, fill the scoop with about a quart of sand, close dampers (if used) and put reverse-lever near full stroke, then open regulator wide, insert the end of the scoop in the round hole in the fire-box door, and allow the sand to be drawn out of the scoop through the fire-box and flues and out of the chimney; sanding is best done when the engine is working hard up a grade.

(7) Black smoke shows incomplete combustion, and should never be allowed to be emitted from the chimney, as it only fills up the flues with carbon, which, besides being a non-conductor of heat, is also a great source of waste of fuel. If a bluish-colored smoke or fumes are seen coming from the chimney, it is a sign that the burner is cut down too fine.

(8) When putting out the fire, the oil-valve should always be closed first, then the atomizer-valve (in their case, steam), then the blower. The oil-valve is always the last to be turned on, and the first to be turned off.

(9) Never go near an open tank with a lighted lamp or torch, as at any time an explosion may occur, especially if the oil used has a low flash-point.

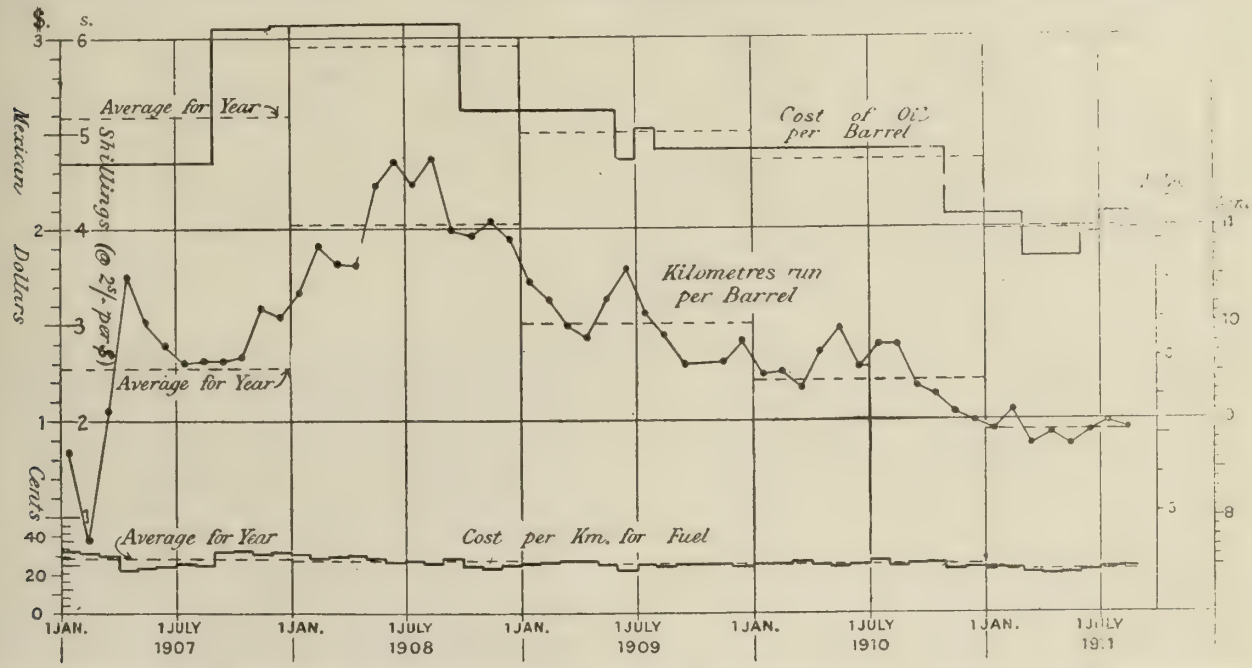


Fig. 3.—Diagram Showing Cost of Fuel-Oil, and Distance Run per Barrel, from January, 1907, to August, 1911, on The Tehuantepec National Railway.

Round House or Shed Work.

An oil-burning engine has a great many advantages over a coal-burner, but this is specially noticed in the round-house or shed when squaring up an engine after a day's run. There are no fires to be raked out, no flues or smoke-box to be cleaned (the smoke-box door of an oil-burning engine need be opened only once every three or four months for cleaning purposes); there is no coal to be sacked, weighed, or otherwise handled, and oil-burning engines do not carry fire-rakes, prickers, flue-brushes, shovels or picks, so that all these things, besides other minor details, represent a great saving in engine equipment.

Among other advantages are the rapidity with which steam can be raised and the facility with which the boiler

can be forced when greater calls are made. The author has in a special case of necessity raised steam in a dead engine to a pressure of 130 lbs. per square inch in 50 minutes from cold water, without any serious effects on the boiler, whereas in a coal-burner from 2 to 3½ hours is needed to raise steam if no jet from a live engine is used.

Another very great advantage is in switching, or shunting, or standing pilot, when engines frequently have to stand in steam for hours at a time. The burner can then be cut down or extinguished, thus effecting a great saving in fuel, as an engine will always retain a sufficient amount of steam to start the burner or atomizer again, and any danger of the fire-box or crown-sheet being injured through the water getting too low is entirely obviated. The heat lost while standing is the same whether coal-fired or oil-fired.

Effects of Oil-burning on Fire-box, Flues, Etc.

Oil-burning is no more injurious to a fire-box or flues, etc., if ordinary care be used, than coal burning; in fact, from the author's experience it is not so hard on a fire-box as coal burning, for it is quite noticeable in the fire-boxes of coal-burning engines that stay-heads, plate edges, flue-ends, and crown bolt-heads show signs of wear, corrosion or burning, while in their oldest oil-burning engine not any of these signs are noticeable, everything being clean and in good condition.

This company uses steel boxes with wrought iron tubes and copper ferrules. A set of tubes will last and remain perfectly tight from 2½ to 3½ years, when they may have to be taken out to be re-ended. Some of the engines are working to-day with tubes over four years old, many of which are as tight as the day they were put in. Some of the wrought iron tubes are being replaced by mild steel, because, after the holes in the tube-sheet get worn, tubes of steel stand the expanding better; but at present those that are in service have not been in use long enough for one to form an opinion of them as compared with wrought iron.

Oil Burning Locomotives in Mexico

Some people are of the opinion that more than 2 per cent. of sulphur in fuel-oil is injurious to the fire-box, but as the amount of sulphur in the Texas oil that the company has been using is below 0.75 per cent., no ill-effects have been noticed. As there are coals which show as high as 3.5 per cent., the author does not see why sulphur should be more injurious in oil than in coal.

Engine Performance.

Although the engine tonnage has practically doubled since 1908, the author gives the following statistics, Fig. 3, for every month from January, 1907, to August, 1911:—

(1) Cost of fuel-oil per barrel of 42 gallons (Mexican currency);

(2) Cost per kilometre for fuel (Mexican currency); and

(3) Kilometres run per barrel of oil.

It must be understood that since about the middle of 1909, all engines are loaded down to their capacity, single trains averaging 750 to 800 tons behind the drawbar. As the road-bed is by no means level, helper engines are used over certain sections where the grades are long and heavy, so that this will explain the decrease in kilometres run per barrel of oil between 1908, 1909, 1910, 1911, as the tonnage per engine has been increased to the maximum.

Oil-Fuel.—Montly Averages.

During	Cost of oil per bbl. Dollars (Mexican)*	Distance run per bbl. Miles.
1907	2.585	5.928
1908	2.957	6.855
1909	2.502	6.209
1910	2.356	5.843
1911 (8 months)	1.990	5.520

*The Mexican dollar is reckoned at 50 cents Canadian currency.

The cost of fuel-oil per barrel of 42 U.S. gallons as charged out every month is made up of the following items, and also depends upon whether there is any shortage or overage when the inventory is taken at midnight on the last day of each month; this accounts for the variation in prices:—

(1) Price of oil per barrel f.o.b. in ship's tanks at delivering port (Puerto Mexico).

(2) Commission to purchasing agents in United States.

(3) Consular invoices.

(4) Inspection fees for inspecting cargo in ships' tanks at shipping port.

(5) Stamps.

Items 2, 3, and 4 only refer to oil purchased out of Mexico.

Based on tests which have been made, the company reckons three-and-a-half barrels, or 147 U.S. gallons, of oil as being equal to one ton of coal of 1,000 kilograms, or 2,204 lb. or three-and-a-half barrels of oil equal one unit of fuel.

Mexican Fuel Oil.

In August, 1911, the company received the first cargo of a native or Mexican fuel-oil under a contract with the "Campania Mexicana de Petroleo," El Aguila, S.A., at a price of $1.75 (Mexican) per barrel of 42 U.S. gallons delivered into railway company's tanks at Puerto-Mexico. This oil, which is used in its crude state as fuel, is jet black in color, thick, and has a heavy asphalt base, and although the company has not used it sufficiently long to be able to compare it with the Texas oil, it may be of interest to state a few of the difficulties met with when first they began to use it.

As this oil is thicker than Texas oil, heaters have to be used in the engine-tanks, but it has been found that if this oil is heated up to about 150° F. (which can be done with Texas oil), great difficulty is experienced in getting the burner spray to light, and that the oil settled very thickly at the bottom of the tank. It would not run through the pipes to the burner, and could only be burnt effectively by mixing a fresh supply of oil with it. In order to burn this Mexican native oil successfully, it requires to be only just warmed. When using this, a large piece of carbon or cokelike substance is formed in the fire-box, and grows up from the bottom of the pan or grate directly under the burner-mouth. This may vary from 6 by 4 by 4 inches to 12 by 10 by 8 inches in size, growing up in such a manner as almost to smother the burner-mouth. The analysis of this substance is as follows:—

Ash	1.25 per cent.
Sulphur	7.89 "
Carbon	90.86 "
Asphalt	nil

It shows to a certain extent that there is incomplete combustion, which can be remedied by admitting more air; but this cannot very well be done without affecting the steaming qualities of the engines. However, by raising the burner slightly these lumps of carbon have decreased in size, and it is hoped eventually to adjust things in such a manner as to prevent their forming at all.

The analysis of two cargoes of this Mexican crude fuel-oil is as follows:—

	No. 1.	No. 2.
Specific Gravity @ 60° F.	0.944	0.942
Baume Gravity @ 60° F.	18.4°	18.8°
Flash-Point (closed)	78° F.	102° F.
Flash-Point (open)	104° F.	120° F.
Fire Test	165° F.	180° F.
Viscosity @ 100° F.	1,080 seconds (Redwood)	920 seconds (Redwood)
Sulphur	3.44 per cent.	3.35 per cent.
Calorific Value	10,971 calories	10,610 calories
Color	Black	Black
Water	nil.	0.5 per cent.
Asphalt		37 per cent.
Carbon (coke)		12 per cent.

It may be explained that the 37 per cent. asphalt is obtained by distilling off the distillates from the crude until only 37 per cent. residue is left, which consist of asphalt.

The author regrets that at this time he is unable to go deeper into this subject.

DEVELOPMENTS IN MACHINERY

A Record of New and Improved Machinery Tendtng Towards Higher Quality and Economical Production in the Machine Shop, Blacksmith Shop or Planing Mill.

NEW GEOMETRIC DIE HEADS.

WE illustrate herewith the new style "D.D." self-opening and adjustable die-head which has recently been brought out by the Geometric Tool Co., New Haven, Conn. This die-head has been specially designed for use in the turret of the Cleveland Automatic Screw machines, but can also be employed on other automatic or semi-automatic machines in which the requirements of operation are substantially similar. It is made regularly in five different sizes, known as the 5-16, 9-16, $\frac{3}{8}$, 1 and $1\frac{1}{2}$-inch Style "DD" Die-heads, the dimensions representing the maximum diameter of thread which each of these die-heads is designed to cut.

The construction is clearly shown in fig. 4. Tne dies are held on splines of liberal size at one side of the openings, in which they are a close fit, effectively preventing any relative movement, laterally or vertically. Their position with relation to the diameter of the thread to be cut is controlled by similar splines in the shape of cams "C" engaging the slots on the lower faces of the dies. As all four dies are adjusted simultaneously, and are solidly supported as close as possible to the cutting strains, they cannot move away from the work, and the greatest accuracy is assured.

The die-head is not held rigidly as in the case of a solid die, but is supported by a spring mechanism between the head and the shank, which permits the chasers to compensate for any inaccuracy of adjustment of the turret. In other words, the head yields as it comes into contact with the work, allowing the chasers to adjust themselves to the piece. At the same time, it provides for a certain amount of longitudinal movement, independent of the turret feed, allowing the chasers to compensate automatically for any slight irregularities that may exist, thus insuring a uniformly accurate product and eliminating wasters.

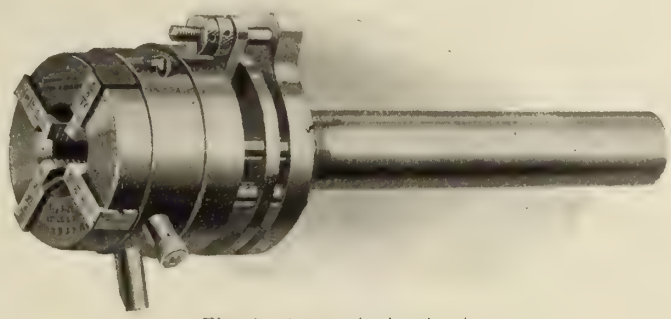

Fig. 1.—Geometric Die Head.

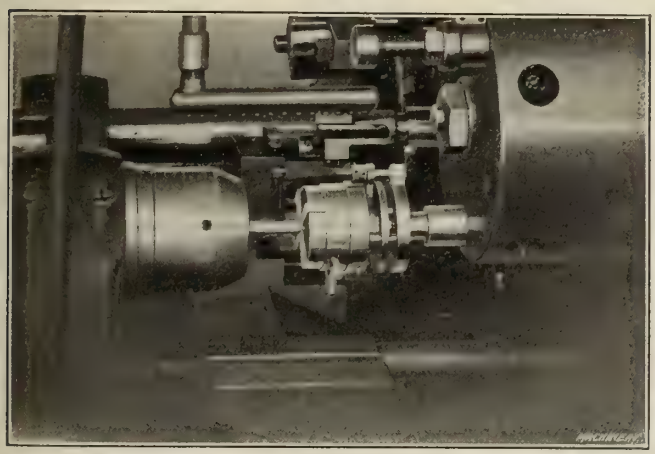

Fig. 2—Geometric Die-head.

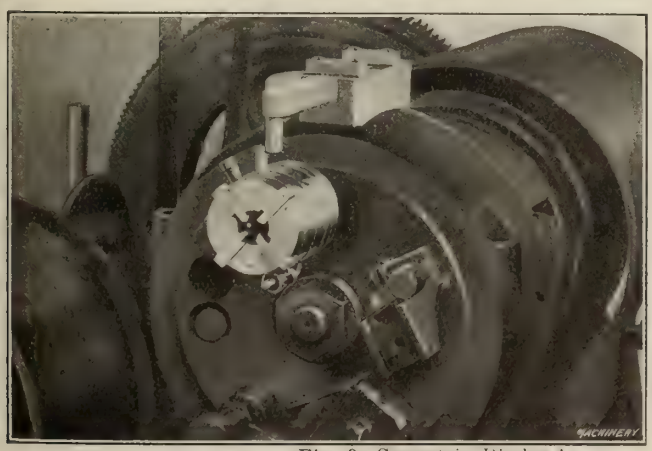

Fig. 3—Geometric Die-head.

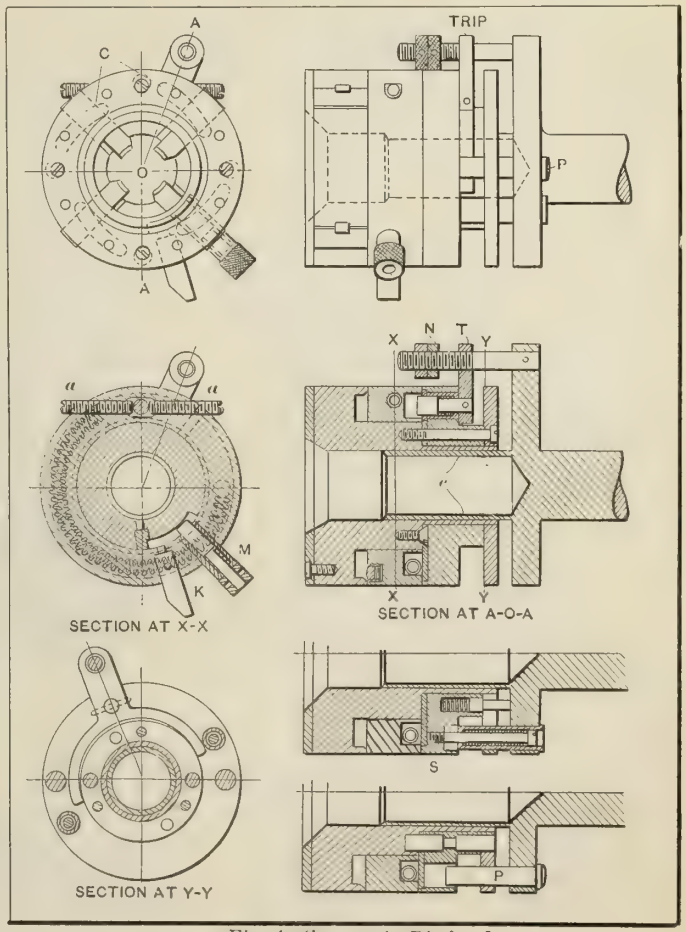

Fig. 4—Geometric Die-head.

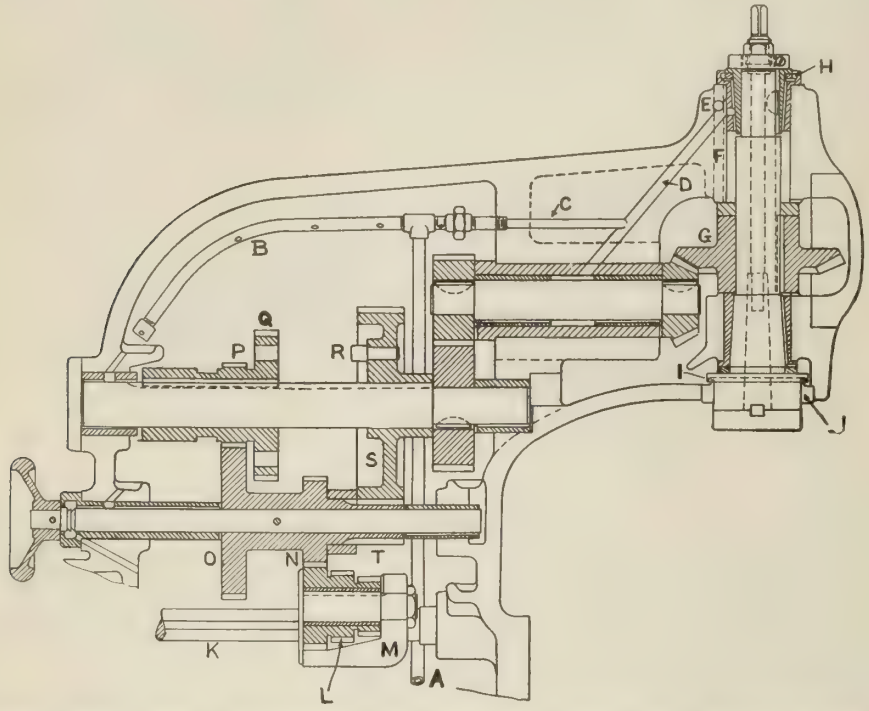
The die-head is not mounted directly on the shank, but is carried on heavy driving pins "P," set into a substantial flange, integral with the shank itself. Further support is provided by a central extension "e" of the shank on which the head is free to move. The travel of the turret determines the length of thread to be cut, but this may also be set to closer limits by means of the lock nut adjustment "N" at the side of the die-head. When the turret reaches the limit of its travel, the die-head has a slight independent forward movement, which causes the lock nuts to contact with the hinged plate "T," releasing the locking bolt and opening the chasers. These lock nuts may be adjusted to allow more or less longitudinal movement, as required by the work, without operating the tripping mechanism. A micrometer adjustment, controlled by two accurately fitted screws, "a," is provided at one side of the head. By means of this, quick and accurate variations may be made in the diameter of the threads for a tight or loose-fitting screw, as desired.

As shown by figs. 1 and 4, the die-head is equipped with a closing pin, "K," designed to close the chasers automatically by the rotation of the turret in conjunction with a closing bar fastened to the turret housing, as seen in fig. 3. In fig. 2, the thread has just been completed, and the tripping mechanism is about to open the chasers, preparatory to moving back off the work. In fig. 3 the closing bar on the machine is making contact with the closing pin "K" on the die-head, thus closing the chasers ready for the next screw.



Vertical Spindle Milling Machine Detail.—The Kearney & Trecker Co., Milwaukee, Wis.

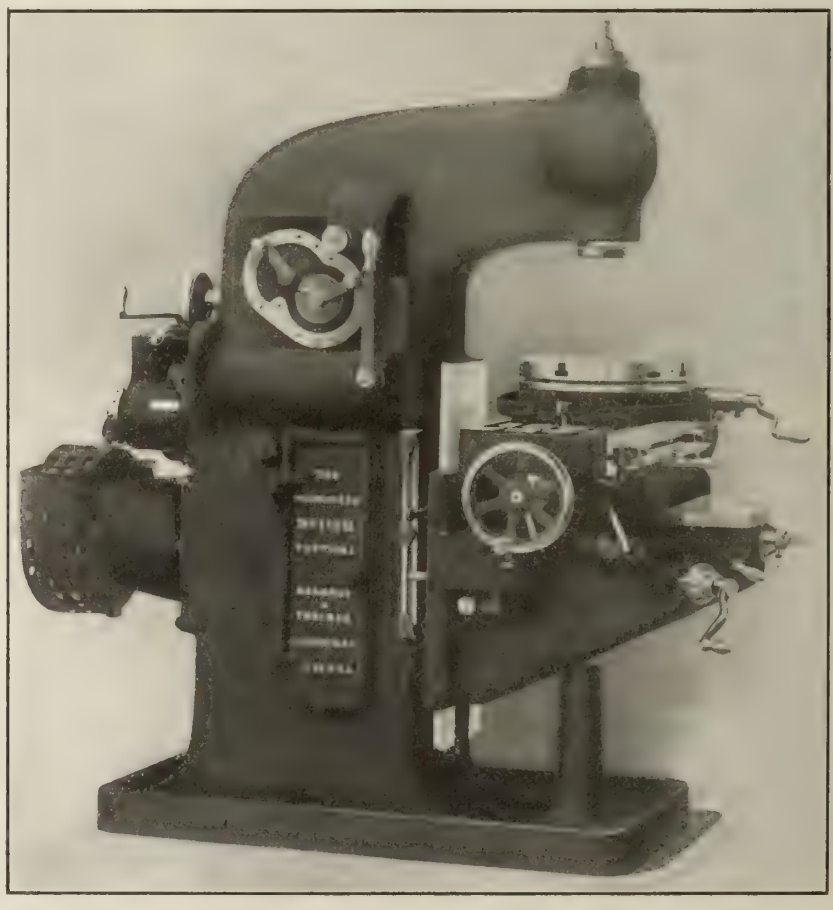
VERTICAL SPINDLE MILLING MACHINE.

THE text and accompanying illustrations refer to a vertical spindle milling machine recently added to the product of the Kearney & Trecker Co., Milwaukee, Wis. It will be noted that there is considerable similarity between this and the horizontal type milling machine also made by this firm; the differences in driving and feed mechanisms having reference to dimensions only. The construction of the knee, saddle and table are also similar to the horizontal design, the knee being of box section without the usual slotted top. In this machine, a departure has been made from the usual practice in vertical spindle machine design of the knee type; the spindle depending entirely on the knee for its vertical adjustment.

System of Lubrication.

The system of lubrication is the same as that employed in the horizontal spindle machines, with the addition of necessary details to take care of the vertical spindle; much of the arrangement is wholly original. The line drawing shows clearly the construction of the spindle and the means employed for its lubrication. The boxes are bronze with the spindle taper on the lower end, and a sliding sleeve, also taper, on the upper end, which enables the wear to be taken up by the collar at the upper end of the spindle. The machine is lubricated through the pipe, A, the pump in the base of the machine being the simple spur-geared type.

It delivers oil to the perforated distributing pipe, B, which lubricates thoroughly all of the horizontal bear-



Vertical Spindle Milling Machine.—The Kearney & Trecker Co., Milwaukee, Wis.

ings and gears, these being so constructed that the oil cascades downward from one to another. It will be noted that these bearings are grooved in such a way that the oil can flow freely through them. This prevents any foreign substance in the oil from lodging in the bearings; the rapid flow washing out any such impurities. A hole, C, is drilled through the main casting by which the surplus oil flows into the passage, D. Engaging with this hole is a horizontal hole connection, E, with the vertical hole F. The hole, F, is plugged at the top, the object being to provide an overflow of the surplus oil, so that in effect a reservoir is maintained in contact with the upper bearings at the height of the hole E. The surplus oil, flowing through F, discharges onto the gear G, lubricating it thoroughly, from whence it flows downward through the horizontal bearings at the front of the machine, overflowing successively each pocket and cascading downward the same as for the back bearings.

The grooves in the upper spindle box are so constructed that the oil is carried upward into the annular groove, H, thoroughly lubricating both thrust collars and bearings. The oil discharged from the gear, G, flows through the lower spindle bearing on to the collar, I, and is prevented from running downward over the end of the spindle by the collar, J, which is made oil-tight in the main frame of the machine.

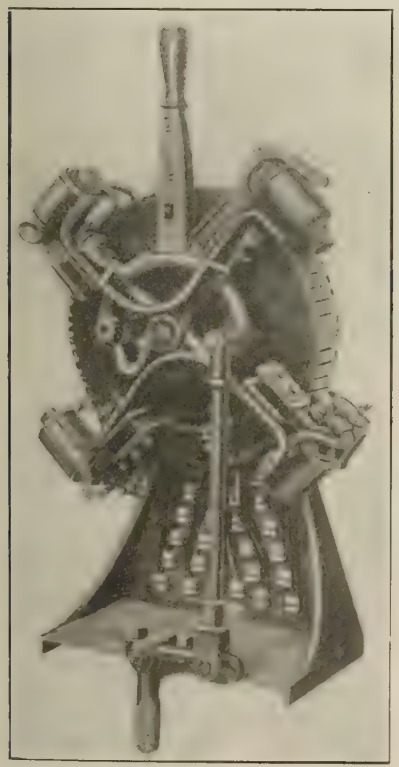


Fig. 1.—Front View of New Concrete "Grindstone" Crane Controller.

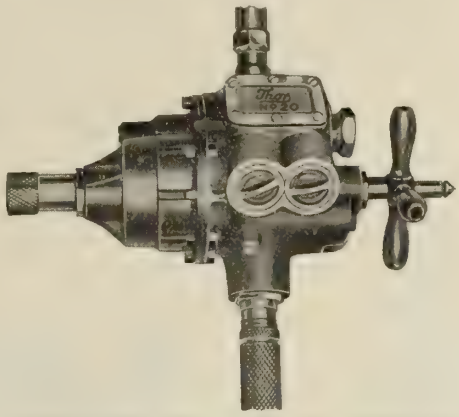
Constructional Details.

The front end of this spindle is of the firm's well-known flanged construction with hardened steel drive collar. This can be removed, and permits face milling cutters to be screwed solidly against the flat face of the spindle, which is always protected from injury



A New "One Man" Drill—The Independent Pneumatic Tool Co.

by the hardened collar referred to, and, therefore, maintains its accuracy. The machine has 18 spindle speeds in geometrical progression, running from 15 to 354 r.p.m.; these 18 speeds being obtained by the use of ten gears only. One of these is located on the shaft, K, which engages with the middle step of the three step cone, L. The latter is an idler carried in the swinging frame, M, which is supported on one side by the shaft, K, and on the opposite side by a pinion, so that there is no overhang whatever to the idler, L. The three steps in the idler, L, are arranged so that they can be engaged successively with the gears, N and O. This gives six changes of speed. The spindle sleeve gears, P, and Q, are arranged to engage with O and M, and also slide into engagement with the pin R on the large drive gear S, which in turn engages with the pinion T for slow rotative speeds. This again gives three changes of speeds, which, combined with the six obtained through the medium of the cone, L, gives 18 changes of speeds in all.

The machine has an automatic table feed of 24 inches, automatic cross feed of 12 inches and can be lowered 18½ inches from the end of the spindle; the vertical feed also being automatic. The work table has an operating surface of 11½ x 38⅜ inches. The rotary table is 14 inches diameter on the working surface, 18 inches diameter over the oil pan and is 5 inches high. The driving pulley is 14 inches diameter for 4-inch belt and runs 150 r.p.m. The pulley is protected by a neatly designed guard, made of perforated sheet metal, and is so constructed that it can be turned to any position around the pulley so that the belt may come from the line shaft directly overhead or from any angle, even to the extent of coming through the floor from a line shaft underneath. No countershaft is employed, since none is needed.

A NEW "ONE MAN" DRILL.

THE Independent Pneumatic Tool Co., of Chicago, New York, Pitts-San Francisco and Atlanta, have recently placed on the market a new "One Man" drill, equipped with compound planetary gears, which is particularly adapted for drilling, tapping and screwing in stay-bolts and studs of all sizes up to 1¼ inches. Heretofore, such work required at least two and sometimes three men to lift and balance a portable machine with sufficient capacity to perform this work, a circumstance which accounts for the new and appropriate designation of "One Man" drill.

It is, of course, of the reversible type, weighs but 20 pounds equipped with a No. 3 Morse taper socket, and, like all "Thor" drills, has Corliss valves with which users are familiar.

A NEW CRANE CONTROLLER.

THE well-known "grindstone" type of controller used extensively in connection with direct-current motors operating cranes, hoists, steel mill machinery, etc., has proven eminently satis-

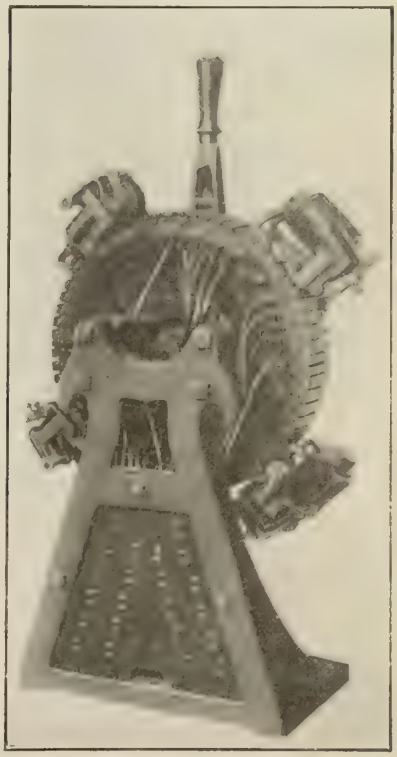


Fig. 2.—Rear View of New Concrete "Grindstone" Crane Controller.

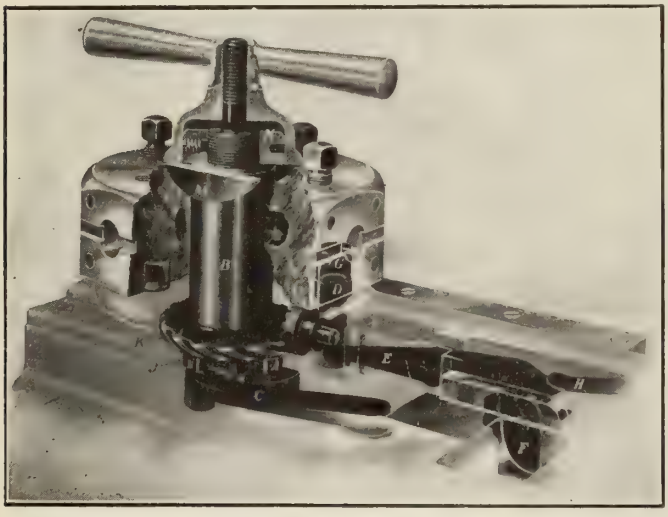
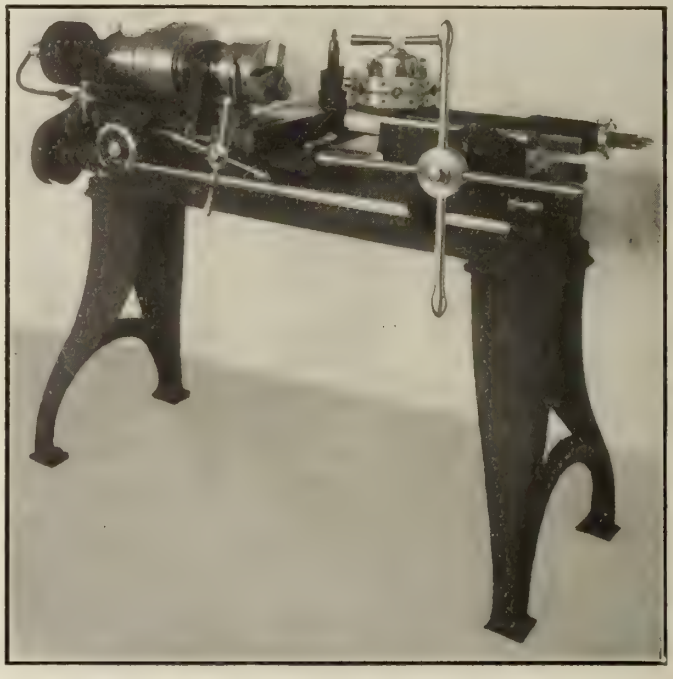
factory. It has recently undergone a refinement, however, which will still further increase its value by simplifying its construction and increasing its durability. As shown in the illustrations, the controller consists essentially of a cast iron frame on which is mounted a stationary disc carrying the contact pieces and cross connections. Pivoted to the center of the disc is the switch arm with four brush holders. The resistors can either be mounted on the frame or separate.

As a result of a series of experiments, the Westinghouse Electric and Manufacturing Co. has recently placed on the market controllers of this type in which the disc is made of concrete instead of stone. By a special treatment, the concrete disc is made a thorough non-conductor and at the same time moisture resisting. The use of concrete permits the cross connections between the segments to be made within the body of the disc, thereby giving the disc a "reinforced" concrete construction and at the same time producing a more compact piece of apparatus. The concrete disc with its self-contained cross connections also gives the controller a neater appearance than the older type.



Turret Indexing Mechanism—The Garvin Machine Co.



No. 22 Monitor Lathe—The Garvin Machine Co.

Figs. 1 and 2 are front and rear views, respectively, of the new concrete "grindstone" controller. In this particular piece of apparatus, the resistors are separate and not shown. The contact pieces are attached to the disc by screws in the same way as in the older type, and are as easily renewable. A blow-out coil of asbestos insulated wire is mounted on each brushholder to disrupt the arc formed in opening circuits.

THE GARVIN No. 22 MONITOR LATHE.

THE machine shown herewith is a No. 22 Monitor Lathe regularly manufactured by The Garvin Machine Co., New York City. It is equipped with automatic power feed to the turret slide, which is under trip of individual stops, controlled by the rotation of the turret. It also has a cross slide, under adjustment by screw and hand wheel, shown located on the bed in front of the head, operated by the left hand. When the end motion is not needed, the slide can be securely bound to the guide-ways.

The special feature of the illustration is the automatic chuck equipment, which has proven to be a large labor saving outfit. Parts may be put in and taken out of the chuck in a very small fraction of the time it takes to operate the ordinary type of wrench chuck, thus reducing to a minimum the non-productive time consumed in operating a machine. As noted in the illustration, the air cylinder is at the rear end of the spindle; the pressure being let into this cylinder, forces the piston endwise. Directly connected with the piston is a rod reaching to the multiple wedge plug which operates on corresponding multiple wedge grooves, located in all three of the chuck sliding jaws. The chuck shown is what is known as the 6 inch, three-jawed, adjustable blank jaw. The grip is controlled entirely by the air pressure used. It is non-yielding, and always has a tendency to tighten. In handling delicate pieces proper reduction of grip can be arranged, by using a reducing pressure valve on the line of pipe between the source of supply and the operating valve.

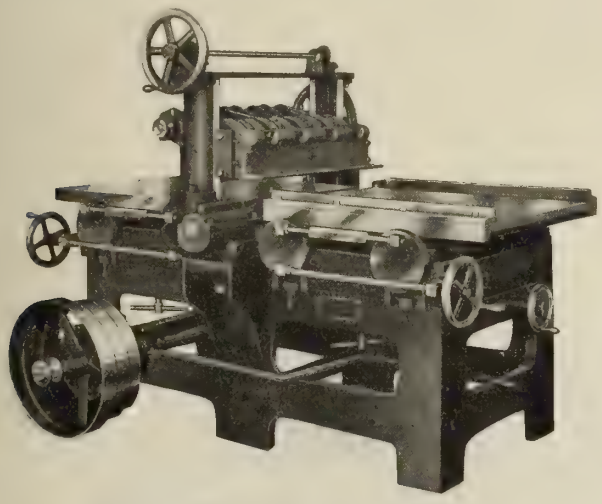
The manufacturers are prepared to furnish spring operating mechanism for factories not equipped with air pressure. In a recent demonstration of the gripping power of the three-jawed chuck, operated by a heavy spiral spring, the chuck used being the 9 inch size, fitted to a No. 6 geared head turret lathe of standard make, a machine steel disc 8 inches in diameter and 1 inch thick, cut from bar stock, was inserted in the chuck jaws, and a 1¾ inch high speed twist drill was forced through the steel plate, followed by a second operation, wherein a grooving tool ¾ inch wide was let into the face of the blank on a circle of 7 inches diameter to a depth of ½ inch. This was, followed by a third operation, the cross slide tool taking a 3-16 inch cut off the entire face of the blank. Naturally the back gears were used, giving the full belt power to the cut. Frequently the belt would slip, showing that the grip of the chuck jaws was up to the full belt power of the machine. The pressure used for closing the jaws on the work automatically releases the brake and starts the rotation of the spindle. The removal of the pressure, either air or spring, stops this rotation and opens the chuck jaws to their full limit. Three-jawed chucks have been described above, but two-jawed chucks of various sizes and styles are furnished.

As it will be seen by the cut, the turret is of hexagon shape, having six flat surfaces with four capped-screw holes for securing rigidly either tools or fixtures to these faces. The turret rotator as now furnished on monitor lathes, is made of one piece as shown in letter B of accompanying cut. It is hardened and ground on the cylindrical fits, and is secured to the rotating turret by two Woodruff keys, shown by letter M in cut.

THE FALLS PATENT UNDERCUT FACE PLANER.

WHEN the power-feed rip saw was first put on the market, it did not take long for progressive manufacturers to recognize its superiority over the old style hand-feed rip saw. Since the advent of the power-feed rip saw, another machine has been brought out. It is the undercut face planer, and as a labor saving device, bears the same relation to the hand-buzz planer, as the power-feed rip saw bears to the band-feed saw.

The illustration conveys an excellent idea of the general construction of the Undercut Planer. It will be noticed that there are four rolls, each acting independently of the other. This means that narrow strips, no matter how badly warped may be fed under each roll at the rate of 15, 30 and 45 ft. per minute, and the quality of the work will be absolutely perfect. Wide stock is worked in this machine as easily as narrow, the rolls being so designed that they get a grip on the board sufficient to carry it forward without exerting enough pressure to spring it down, even if the stock is so crooked that the cut is not carried all the way across the board. They rise and fall with its irregulatities and conform to the crooks in the stock.



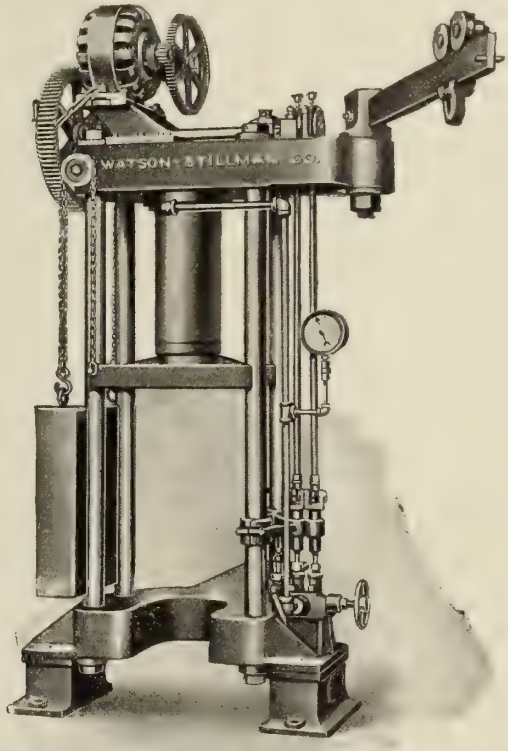
The Falls Patent Undercut Face Planer, No. 820.—The Canada Machinery Corporation, Galt, Ont.

The frame is heavy and cast in one solid piece, giving the machine a firm foundation. The large hand wheel adjusts the feed rolls to accommodate stock up to six inches thick on the regular machine; and up to three inches on the special short stock machine. The cylinder and spindles are a solid forging of high carbon-steel slutted on two sides. The arrangements for adjusting the tables is such that the edge is kept constantly within 3-32 of the knives, thus affording a good chip breaker. Other interesting features are the provision made for cutting hollow and crown points as well as surfacing stock, and the fact that the operator cannot get his fingers in the knives.

The machine is a product of the Canada Machinery Corporation, Galt, Ont.

CONVENIENT HYDRAULIC LOCOMOTIVE BOX PRESS.

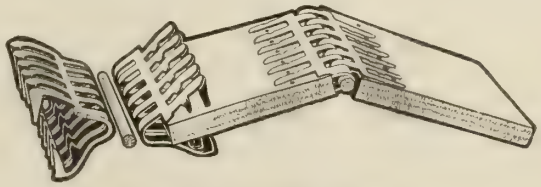
THE press which we illustrate herewith was designed for Mr. F. F. Gaines, superintendent of motive power of the Central Railroad of Georgia, and has proven very succesful for pressing journal box bearings into and out of place. It is also useful for broaching, key-seating, putting gears on shafts, pressing bearings, handling mandrels and general railroad shop work where heavy pieces have to be forced together. A crane bracket and beam are extended from one end so that the work may be swung into the press without hard manual labor. A back-geared motor mounted upon the pedestal on top of the press drives the pump shaft. Upon the other end of this shaft are two pump eccentrics. The pump pistons are both ¾ in. diameter by 2 in. stroke and the pedestal legs act as reservoirs for the pump. The operating valve shown is a single screw stem valve which releases the pressure from the work when open and starts the ram down when closed. A safety valve is used in connection with the pump to stop dangerous overload. The press, made in two sizes, 60 and 100 tons capacity respectively, and furnished hand or belt driven as desired, is built by the Watson-Stillman Co., 50 Church street, New York.



Convenient Hydraulic Locomotive Box Press—The Watson-Stillman Co., New York.

ALLIGATOR STEEL BELT LACING.

THE requirements of every modern manufacturing plant demand the risk of shut-down to be not only reduced to a minimum as regards frequency, but at the same time, when the unavoidable does happen, that the period be restricted to the utmost in duration. Belt drives, from time to time, necessitate, due to repair requirements, it may be, either the stoppage of a single machine, a sectional group of machines



Alligator Steel Belt Lacing.

or perhaps the whole factory, should the main drive belt give out. In such circumstances, the enforced idleness means a lesser or greater loss, and naturally it is the part of wisdom to not only have efficient operative equipment ready for the emergency, but also such as is easily and quickly applied. The alligator steel belt lacing which we illustrate and describe, is claimed to fulfill both these purposes admirably, in addition to other attractive features. Official tests go to show that the "Alligator" joint has a strength equal to 60 or 70 per cent. of that of the best grades of belting procurable, and that the joint is in every respect, perfectly flexible.

Alligator steel belt lacing is adaptable for use on leather, rubber, balata, cotton or canvas-stitched belting, and consists of a separable lacing, hinging on a raw-hide or sectional steel rocker pin.

The flexible joint insures quick contact with the pulley, whether the belt is run with either or both sides in service, and as the lacing engages both sides of the belt alike, the strain is thrown in direct line of the pull, making a joint which is easy on the belt, and where applied according to directions will stand any belt strain, under any conditions of service. With rubber or textile belting this lace overcomes the tendency to fray at the ends, as the members of the lace clamp the stub so as to protect them. It will work perfectly in contact with an idler, and no punch holes are required.

The teeth on each side of the lacing enter the belt on different lines of perforation; each prong has two teeth, the longer clinching through belt, the shorter point on opposite side of prong giving great additional strength. Both enter the belt so that the pull is against the edge of the steel and not against the flat. This avoids weakening the belt, and in rubber and textile belts does not cut the long threads in which lie the strength of that class of belting.

Being separable, this lacing is especially adapted for use on overhead belts the ends can be dropped down, the lacing applied and hinge pin inserted after belt is returned to shafting, by taking out pin, belt may be temporarily removed from service, lengthened by inserting a stub section of belting or shortened by cutting off excess from one end and using half of a new lacing.

The connecting bar between the prongs is indented on the under side to allow it to be broken into required lengths (cutting pliers not being required) and the use of a single section on any width of belt up to 12 inch. The indentation also insures that in use over heavily crowned pulleys the bar may be broken without weakening the lacing, as each indentation separates a full staple which retains its efficiency.

The sectional rocker hinge pin consists of two specially formed steel wires having oval faces with lugs on back to fit in between loops of the hinge and keep it from working out. In service, the sections of the pin remain stationary in the loops of the lacing and give the necessary flexibility to the joint by rocking on their oval faces. When using the rocker pin, cut two pieces just alike, same length as bar of lacing, having small lug at one end; reverse one piece, put smooth faces together as shown in cut and insert in lacing with round back fitting the loops of lacing, having lugs between loops of hinge.

The "Alligator" steel belt lacing is made by the Flexible Steel Lacing Co., Chicago, and the Canadian agents are the Crescent Oil Co., Hamilton, Ont.

BUILDING RAILWAY ENGINES AND COACHES IN NEWFOUNDLAND.

By Ben Brigden.

AFTER many years of railway service in the Island of Newfoundland, the Reid-Newfoundland Co. has, perhaps, reached its goal—that of constructing locomotives and coaches for use on its own lines throughout the island. This expectancy was realized a short time ago, as may be seen by the accompanying illustration, and to anyone familiar with the conditions appertaining to Newfoundland railways in days gone by, the present successful achievement and, necessarily, new industry established, are, certainly beyond the most sanguine expectations of the then few great railway philosophers in that territory. The recent opening of the newly constructed section of the Trinity-Bonavista branch line will serve as a further impetus to the undertaking, while the public, who travel, will have the pleasure of knowing that these added conveniences of civilization and their surrounding commerce are the handicraft of their fellow countrymen and the products of their own province.

It is only necessary, at this time to mention, in order to give our readers a general comprehension of the size and capacity of this locomotive that, in the face of the knowledge that Newfoundland winters are of an exceedingly vigorous and prolonged nature, to build, or even attempt to build, anything other than first class, or, to be still more precise, anything inferior to Canadian or United States manufacture, would be a step in the opposite direction to that which characterizes this progressive Reid-Newfoundland Company. The constructional details of this engine consist of the best material obtainable, and everything, with the exceptions of the springs, was turned-out in the Reid shops at St. John's, by expert mechanics. Other engines are in course of erection, and not only does this good work apply to "iron horse" building, but it also amply fits concerning the mail coaches and passenger cars that to-day are being built by the same energetic firm and distributed over their one thousand miles of road, which, figuratively speaking, encircles the whole country.

A Product of the Reid-Newfoundland Works, St. John's, Newfoundland.

TRAINING PATTERNMAKERS.

The Board of Education of New York City has approved a resolution relative to an agreement between that body and the Patternmakers' Association of New York, for the training of patternmakers' apprentices in the evening vocational schools of the city. The Patternmakers' Association has agreed that it will direct its apprentices to attend the evening school and it is proposed that the courses of study be conducted by the regular teachers and the practical workers of the association.

The Board of Governors of the University of Toronto has appointed Mr. George A. Guess to the position of Professor of Metallurgy in the Faculty of Applied Science and Engineering.

Vol. VIII. FEBRUARY, 1912 No. 2

A FEATURE OF INDUSTRIAL SUCCESS.

IT is a well established fact, and deeply imprinted in most of our minds through its continually operative effect, both as regards the individual employer and a corporation's managing directorate, that unless we keep at least abreast of the times in which we live, there is the gloomy certainty just right ahead, of our being completely swamped by and engulfed in the tide of industrial progress.

It is surprising to find, even in this comparatively new country, manufacturing enterprises being conducted along the most primitive, unsystematic, inefficient, and, of course, uneconomical lines, and with a settled determination to persist in following the well-worn groove still further. A self-satisfied state of being is apt to take possession of individuals and corporations because of their past and present achievement, and a too liberal rendering of the instruction, "take no thought of the morrow," seems to be the mainspring of their business code. While sympathising to some extent with this attitude of passive resistance adopted, it cannot be too strongly impressed on those concerned, that their chosen general policy is suicidal. We sympathise with and admire their passive resistance to the volleys of idle "clap-trap, small talk, empty and meaningless nothings," popularly, but erroneously known as "business maxims," by which they are assailed. An official desk plastered over with such "gems" as "do it now," "don't worry," "yesterday is gone, etc.," may be an impressive sight to some bubble chaser, but to the man who has a vision and reads aright the signs of the times, it looks much like a military general trying to conduct a campaign on a foreign shore without an "Intelligence Department." However, and to return to our subject, comfortable contentment and smug satisfaction with present conditions, large financial distributions of bonuses, dividends and salaries, without regard to an ample appropriation being set aside for pursuing research work, operate just as effectively in the "running to seed" process of the great and presently world-known concerns as does the small, obscure and "self-contentment-drugged" plant in its relative position.

Again, the individual attitude to secure the highest possible achievement must also be that of one with a vision. The ambition to be the bearer of the "Message to Garcia," and the putting of the ideal into practical effect is not attainable by making a billboard of your "den" and an curiosity of your personality. The future of the great industrial corporation, the moderate size or small factory, and of us the individuals contributing to and receiving from either in the shape of investment returns, etc., depends on the establishment of a mutual direct personal co-operation towards further development. Too many individual, industrial corporations, large and small, simply sap and undermine the very foundations of their near future existence by pursuing a policy whereby every cent of profit is demanded on the score of "being only right and just," and too few corporations realize, that unless research and experimental work is amply provided for and diligently prosecuted, the succeeding few years will find them stranded and unable to compete in their particular line. Too many shareholders are so supremely selfish and so painfully ignorant of the laws of cause and effect, that they are prepared to adopt tactics, crude, coarse and even cowardly to secure their pound of flesh. Again, too many employees forget that busy times are not always prosperous times. A large output of machinery or a factory employed night and day throughout the year does not necessarily imply an increased revenue for distribution. On the contrary, it may have been all in the other direction. Employees should, therefore, realize that it is their duty to study diligently the situation so far as their contributory help affects, with a view to disclosing whether the granting of a larger share to them in the form of increased wages, is going to materially injure the company's competitive capability.

If directors, shareholders, and employees showed less suspicion of one another, if they would peer into the future a little more and get a glimpse of the trouble ahead which mutual consideration for each other's interests could easily circumvent, there would be fewer labor disputes, an entire disappearance of the grouchy shareholder, and a less bristly part for the management to tread in successfully meeting competition.

EDITORIAL INDEX FOR 1911.

THE attention of subscribers is drawn to The Canadian Machinery editorial index for 1911, inserted at the rear of the present issue. By opening the binder clips on the last page—that facing the inside back cover—the index may be withdrawn for filing or binding along with the numbers for the year to which it refers. On closing the binder clips again, the current issue is kept intact.

FOUNDRY PRACTICE AND EQUIPMENT

Practical Articles for Canadian Foundrymen and Pattern Makers, and News of Foundrymen's and Allied Associations. Contributions Invited.

WHEN the Tropenas converter was introduced and success assured, it was believed that the steel casting industry had about reached the top notch. Although unable to compete with the open hearth furnace on large castings, for the smaller lines of work the converter could produce steel superior to that of the open hearth. Each system was, therefore, practically in a field of its own. Now, however, with a better understanding, cheapening and controlling of electricity, attention has been drawn to consider the electrical furnace as a still more efficient medium for the production and refining of steel.

About 15 years ago, in a plant where the writer was employed, an attempt was made to melt grey iron in the cupola by electrical means, instead of coke. Sunday was the day selected to try the experiment on account of the fact that the whole power of the plant was required for the purpose. It is not necessary to go into details, further than to say that iron was melted, but so sluggish was it that pouring from the ladle, much less the pouring into a mold, was impossible, Since that time a number of electric furnaces have been designed and, in their operation have given excellent results by producing high grade steel at phenomenal low cost. At an additional cost of $1 per ton, they can transform the most common Bessemer iron into best quality iron suitable for car wheels or automobile and small marine engine cylinders. In fact you can produce just what you desire and know what it is before taking it from the furnace. It is the most practical method for reducing sulphur, and at the same time for obtaining a strong close-grained yet soft iron suitable for machining.

The Gronwall Electric Furnace.

One of the most efficient types of electric furnace up to the present time is the "Gronwall," invented by Messrs. Gronwall, Lindblade & Stalhane, three Swedish engineers of Ludvika. This furnace has some very distinct features, not embodied in others. The two-phase current arc type has been adopted, a procedure exactly opposite to the induction system. Electric furnaces differ from all others in that they receive their heat from mechanical sources, those of the open hearth and converter being heated from a chemical combination. In the mechanical method, you can control the elements of your mixture with certainty, whereas, in the chemical, everything depends upon the nature of the fuel used. Again, comparing the electric furnace with the crucible, there is a bath wherein you can make additions of refining slag so as to make steel to suit any specification desired.

A general view of the Gronwall furnace is shown in fig. 1. It will be noted that there are two carbon electrodes hung perpendicular, being a means of additional strength, compared with some types which have the electrodes hung at an angle inside the furnace, where with the intense heat they become soft and liable to break and drop into the bath of metal. Such a contingency would raise the carbon content and practically make the steel into cast iron, unless the carbon was withdrawn before it dissolved; otherwise, additions of ore and scale, to reduce the carbon present, would have to be made, as in the open hearth furnace, necessitating subsequent deoxidation of the steel before being poured. The vertical electrodes seldom break. The average analysis of the Amphorus Carbon Electrodes is as follows: Carbon, 96 per cent., ash 2.80 per cent., sulphur, .80 per cent. These electrodes are provided with screwed joints, so that they can be fed into the furnace continuously, the consumption being about 100 pounds per charge of a 5 ton furnace.

Their size is 14 inches sq. by 6 feet long, and 1.57 sp. gr. Each electrode is independent of the other, so that if anything goes wrong with one, the other can run the furnace. If arranged in sets, any single unit interference means complete shut down. The current passes from the electrodes to the slag or the metal in the bath, forming

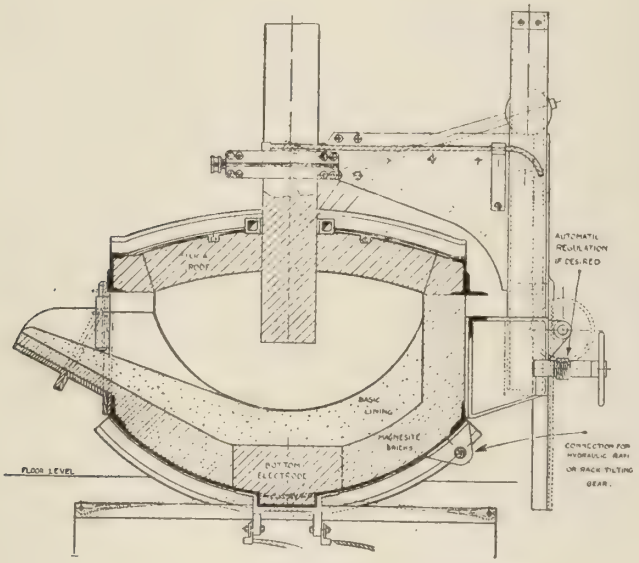

Fig. 2.—2½ tons capacity, electro-metals steel refining furnace—cross section.

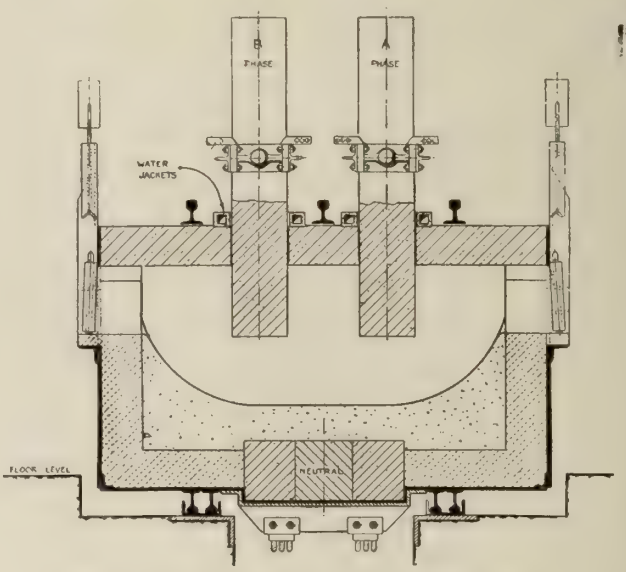

Fig. 3.—2½ tons capacity, electro-metals steel refining furnace—Longitudinal section.

an arc, then through to the basic lining on to a carbon block at the bottom of the furnace.

The main shell of the furnace is built of boiler plate and magnesite brick lining, with a hearth of dolomite rammed therein as in figs. 2 and 3. The roof is made of channel iron in the form of a frame, to hold the silica brick. It is

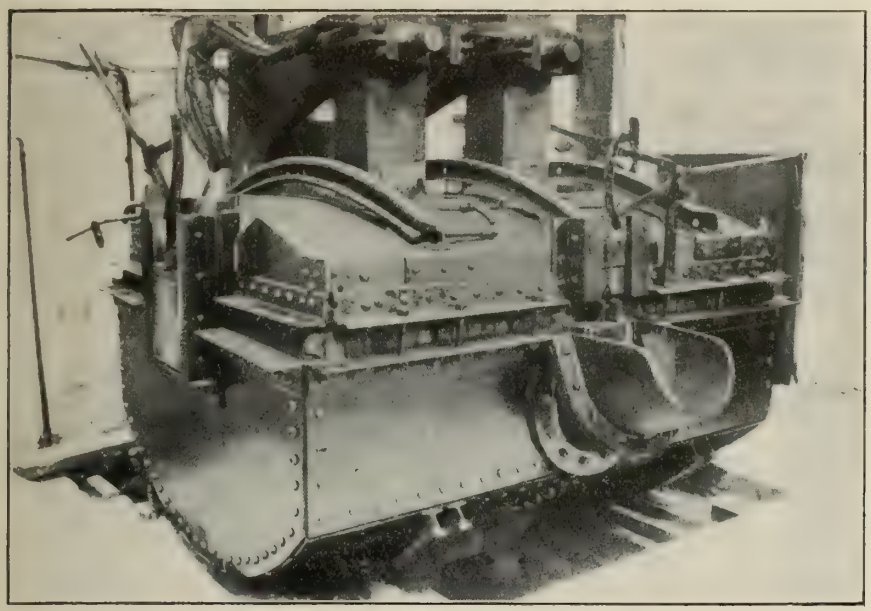

Fig. 1.—2½ tons capacity, electro-metals urnace.

separate from the other lining, so that when repairs are required to the roof, it affects nothing else. Working doors are provided at each end, also at the tapping spout, of a size to suit the requirements of charging. This can be either hot or cold, and if a very large piece is wanted to be disposed of, the top can be lifted off altogether and quickly replaced. At the back of the furnace there is a rachet arrangement for the regulation of the electrodes. This may be done by hand or automatically as desired. The loss of electric energy is reduced to a minimum by the method of gripping the electrodes quite low down. The furnace is tilted by hand or by power, electric or hydraulic. The electrical equipment has been properly taken care of, and there is little difficulty in reducing a high tension to 50 or 70 volts.

Electric Iron Smelting Furnaces.

The same engineers have also designed and patented an electric iron smelting furnace of the cupola type, using charcoal as a reducing agent. This to all appearance is going to hold its own in the manufacture of pig iron, and I believe will be a commercial success especially in Canada where there is such abundance of ore, but so high in phosphorus that it cannot be used in the manufacturing of steel. There are other designers in Canada working along similar lines but as their efforts are still in the experimental stage they cannot at this time be discussed. I have appended the latest report of the Trollhattan furnace operation.

Trollhattan Furnace Operation.

As might have been expected, the first six months' working suggested various alterations in the construction of the furnace. It was, therefore, shut down at the beginning of June last, for the carrying out of these alterations. The plant was again started during the first week of September, and has been at uninterrupted work ever since. During the week from September 3 to September 9, the following results were obtained :—

	Tons.
Pig-iron produced	131.4
Quantity of slag	22.1
Charcoal used per ton of iron	0.336
Pig-iron produced per kw.-year	5.05
Pig-iron produced per h.p.-year	3.79
Current consumption per ton of iron	1,736 h.p.-hours.
Power consumption per ton of iron..	2,351 h.p. hours
Average load	1,357 kw.
Average CO_2 contents in the gas (by volume)	30 per cent.

The current and fuel consumption depend, of course, to a large extent on the quality of the ore. The results for a protracted period during which the same kind of ore was used are, therefore, of interest.

WORKING RESULTS.

	Sept. 3rd to Sept. 30th.
Pig-iron produced, tons	537.9
Quantity of slag, tons	88.9
Iron in the ore, per cent.	67.65
Iron in the ore and lime, per cent...	65.02
Quantity of slag per ton of iron, kg.	165
Charcoal used per ton of iron, kg....	339.9
Average load, kw.	1,407
Average power, h.p.	1,913.5
*Current used per ton of iron, kw.-hours	1,749
†Iron produced per kw.-year, tons..	5.01
Iron produced per h.p.-year, tons...	3.68
Average CO_2 contents in gas, per cent.	29.27
Average analysis of iron :—	
C, per cent.	3.64
Si, per cent.	0.36
Mn, per cent.	0.40
S, per cent.	0.009
P, per cent.	0.018

*According to instruments at the furnace.
†Estimated on the basis of 8,760 kw.-hours per kw.-year.

Comparing these figures with the earlier results, it will be seen that a great improvement has been obtained over the first six months' working results. Per ton of iron there were then used from 2,150 to 3,800 kw.-hours, and for the entire time an average of 2,391 kw.-hours. The ores then used varied somewhat in quality, but it will be seen that a reduction of 20 to 25 per cent. has been effected in the current consumption. Correspondingly, the output of pig-iron per kw.-year has been raised from an average of 3.66 tons to over 5 tons. The charcoal consumption has been reduced from 418 kg. to 340 to 345 kg. per ton of iron, and the electrode consumption has also been reduced. The electrodes now used are supplied by the well-known Planiawerke, and are provided with screw joints so that there are no waste stumps.

The practical importance of the process is best proved by the fact that there are now built or building furnaces for an aggregate of 27,000 h.p., while, in addition, furnaces for about 36,000 h.p. are projected.

NEW APPOINTMENT.

Mr. W. H. Maybank for a number of years foundry superintendent of the Ornamental Iron Department of the Canada Foundry Co., has associated himself with the Dominion Foundry Supply

W. H. MAYBANK.
Representative, The Dominion Foundry Supply Co., Toronto and Montreal.

Co., Ltd., of Toronto and Montreal. in the capacity of traveling salesman. Mr. Maybank is a practical man, and is prepared to give the benefit of his brass and iron foundry experience to those in need of same. The Toronto branch still remains under the management of Mr. F. J. Ross.

THE NEW MUMFORD VALVE FOR JOLT-RAMMING MACHINES.

EVERYONE having experience with jolt ramming machines has appreciated the presence or bemoaned the absence of simplicity in their design.

In the case of jolt-ramming machines, the familiar adage that "nothing is stronger than its weakest part," might well be paraphased to "nothing is tighter than its loosest part." The constant fierce shocks to which all such appliances, whether "shockless" or otherwise, are subject, put simplicity at a premium, for everything about them is struggling for freedom to desert its post. What happened in the story "for want of a nail" was hardly more tragic than what often happens for want of a nut or a pin in a busy, jarring-jolt-ramming machine.

Simplicity of Jolt Ramming Machines.

Jolt ramming machines, per se, are essentially simple:—An anvil, upon which a table, raised by a plunger attached to it, falls to ram a mold, is the whole story, excepting—the account of the valve. The early jolt-ramming valves had in them a piece for each function. No particular inventive faculty is requisite to think of a hook to hang one's hat on—more hats more hooks, that's all. So, it is easy to open something to let the air out and open something to let the air in and shut something else to keep it there; then add a spring, a tappet, a cam or a lot of handy things that may be had without much thought to manipulate these various features. When such a valve is new, it is often as imposing as a brass band, drum major, etc. But, what after all is it? Not unlike the wonderful dog kennel with a little hole for the little dog and a big hole for the big dog.

Valves have been designed to enable the operator to change the stroke of a jolt-rammer while ramming. Result—a useless thing done, and costly, trappy, useless parts to do it. The stroke of a jolt-rammer need never be changed. Give it a stroke long enough to ram the hardest mold, hard enough, and arrange it so that the blow may be modified at will by varying the back pressure on the plunger to give the gentlest blows needed. The operation of the valve will be understood from the following reference to the sectional view of a 24 inch jolt-ramming machine with 72x72 inch table, and capacity to ram molds weighing twelve tons.

Valve Operation.

Air entering at A passes around the stem of the valve B to the bent tube C. From this tube it enters the space in the side of the main plunger at D. Through the port E it reaches the cylinder and raises the main plunger with its mold table. As the lower edge of the packing ring on the main plunger uncovers the exhause port F, the rising shoulder G of the main plunger obstructs the entering air. With the exhaust open and entering air blocked off, the pressure falls rapidly under main plunger, and while table is falling to impact, valve B blows up into the reduced pressure in the cylinder and closes positively the entrance of air. The pressure which forces valve B up is line-pressure introduced through the by-pass H, and this pressure holds B up, with air cut off, until, just before

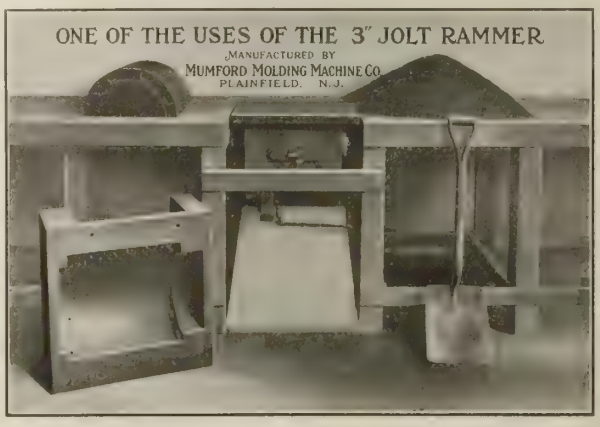

Fig. 2.—3-inch Jolt Ramming Machine on Core Bench, with Knee-pad Operated Valve.

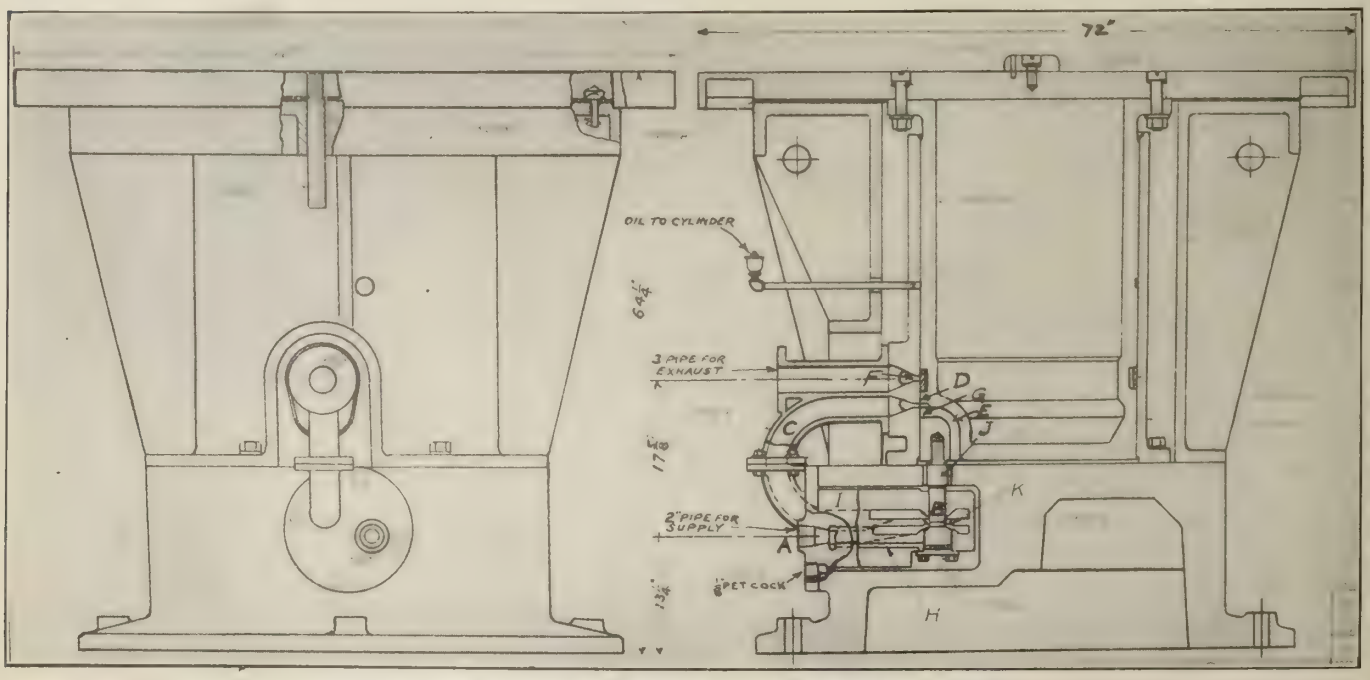
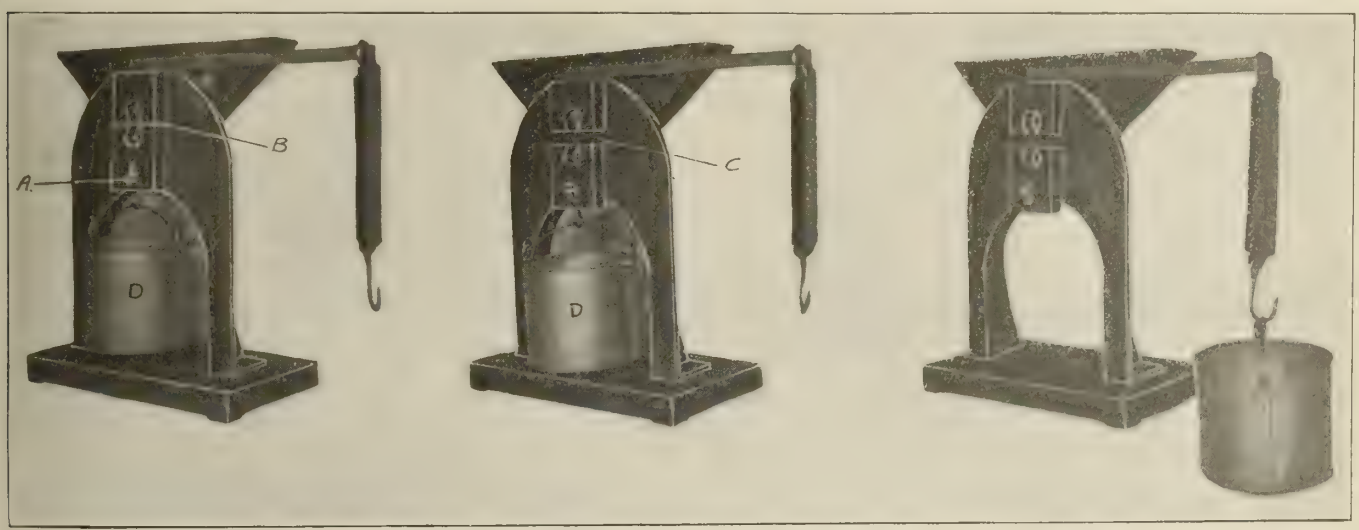


THE NEW MUMFORD VALVE FOR JOLT-RAMMING MACHINES.

impact, the projecting part J of the main plunger forces valve B open and re-admits air for the next blow.

Thus it is seen that the valve of this jolt-ramming machine is unique in that it is actuated by the air independently of the velocity of the rising table, without imposing any burden upon the entering air column. In this it is differentiated from those valves which require that the machine shall have enough reserve capacity to send the table **past** a valve-throwing-point with velocity sufficient to complete the operation and not stall with valve partly thrown. For the above reason, these machines are claimed to give higher capacities than machines with the other valve types. The total absence of springs in the valves or elsewhere in these machines eliminates a source of trouble usually present wherever springs occur. Moreover, simple and sure as is the working of the valve B, it is carried in a readily removable plug I, so that even unforeseen accidents are provided against.

A 3 inch machine of like construction is shown in fig. 2, in quite a usual setting, on a core bench with knee pad operated valve.



THE WADSWORTH CORE TESTING MACHINE.
The first cut shows the machine ready for opening the valve. The second cut shows the test piece broken, and the third cut shows the amount per square inch taken to break it.

A CORE TESTING MACHINE.

FOR many years there has been a demand for some practical means of comparing the strength of various core binders. It is also often important to be able to compare the strength of different core mixtures as affected by changes in sand, oils and binders.

Experiments on Core Mixtures.

Some five years ago, George H. Wadsworth started a series of experiments on core mixtures. The work was carried on jointly by George H. Wadsworth and H. M. Lane, but was dropped for the time on account of lacking the equipment for making accurate determinations. During the past year the work has been taken up once more, and a number of manufacturers have collaborated to carry it through.

During the experimental work, a number of different methods of testing cores were tried. Broadly, the choice lay between a tension and a transverse test. In the case of very strong cores, such as oil sand mixtures used for radiators, some classes of fitting cores, gas stove burners, etc., the transverse test on a one-inch square core 15 inches long gave fair results, but it was difficult to turn out these large cores in quantity without rods, and to be sure that they would not contain mechanical defects which influenced the strength. Then, too, the transverse test on bars of this length was not delicate enough to give a comparison between mixtures of approximately the same strength.

In testing the tension methods, an ordinary Fairbank's cement testing machine was first employed, and this was found excellent for very strong core mixtures, but was not delicate enough for the weaker mixtures common in grey iron, brass, and malleable foundries. There is on the market a small machine operating on the spring principle which was tested for this purpose, but as its price was fairly high and its capacity limited to 50 pounds per square inch, it was not found universally satisfactory, and hence the new Wadsworth Core Testing Machine was developed, as shown in the accompanying illustrations. The core used is the shape of the ordinary concrete briquette, having an area of one square inch in the centre. The core is placed between the jaws when they occupy the position shown at the left, the jaws being closed together as shown at B. The illustration, however, does not show the core in place. The pail D is hung to the lower jaw so that it is supported by the core. The hopper E is filled with shot, and by raising the pin A to the top of the slot in the jaw a small gate at the bottom of the shot hopper is opened and the shot allowed to flow into the pail D. As soon as the weight of shot in the pail becomes sufficient, the core breaks and the jaws separate as shown at C in the central view. As the lower jaw decends, it carries with it the pin A, thus automatically closing the shot valve. The jaw, however, is so arranged that the pail and jaw remain supported upon the pin A without coming in contact with the base of the machine. The pail is then lifted off and hung on the spring balances, as shown at the right of the illustration. To get the full weight which it took to break the core, the lower jaw must be placed in the pail, or a weight equivalent to the jaw must be placed in it. This gives a direct reading of the weight necessary to break the core. As soon as the reading is taken, the pieces of the core are removed from the jaws, the shot poured back in the hopper, another core inserted, and the pail hung on once more, as shown at the left. The operation is very rapid, so that it is possible to test at least two cores per minute with ordinary mixtures.

Practical Use of the Machine.

The practical use of the machine is as follows: If it is desired to test a new lot of sand oil, or binder, two batches of cores are made with the same sand, one using the old binder and the other the new, in the same ratio. These cores should be baked on the same plate in alternate rows. They are then taken out, allowed to cool, and broken. The baking temperature will have consider-

able effect on the strength of the core. but it will affect both samples alike, so that with this method of procedure an exact comparison of the strength of the two binders is possible. It has been determined that variations in the clay content of the sand, and amount of dirt in the sand, or in the shape and size of the sand grains themselves, may have a marked effect on the strength of the core, and hence every new lot of sand should be tested as it comes in. To accomplish this, take samples of the new and old sand, and make with them two lots of cores from a standard binder, as, for instance, a sample of core oil kept for the purpose. These two sets of cores should be baked on the same plate and tested as already described.

A check on the regular running of the foundry may be secured by having one or two plates of test cores made from the regular mixtures each day and baked with the regular cores. If the ovens are running either too hot or too cold, these test cores will not develop the strength they should. This gives the core room foreman an absolute check on the man who is firing his ovens, and on the man who is making his mixtures. It is possible to control the strength of the cores within very narrow limits, but this is not accomplished in the practice of ordinary core rooms to-day, and in these irregularities both as to mixtures and temperatures, lies the cause of great variations and loss of castings, due to irregularities in cores. If the poor cores are sorted out before they go to the molding floor, the firm is still out of pocket an amount equal to the material contained in the cores, including both sand and binder, the coremaker's labor, the core oven fuel, and the necessary expense of handling. The use of one of these testing machines will afford a quick and inexpensive means of checking the daily core room practice. The machine is manufactured by The Wadsworth Core Machine & Equipment Co., Akron, Ohio.

BLAST FURNACE GASES.

IN his presidential address delivered before the West of Scotland Iron and Steel Institute, Mr. Walter Dixon said "that it was now recognized that blast furnace gases used in gas engines could develop not less than twice the power which was capable of being developed in steam engines using gas-fired boilers, and it was a question for each particular works to decide how far, and to what extent, they were justified in using their gas as at present, in an admittedly uneconomical way, or how far, and to what extent, it was reasonable to avail themselves of the demonstrated possibilities of gas power. The case was different with foreign competitors. With them blast furnaces were generally associated with steel and other works requiring power, and the rapid increase in the number of gas engines now employed on blast furnace gases showed to what extent the possibilities had been recognized. The distribution amongst various countries of 1,033,509 b.h.p. of large gas engines was :—Germany, 46.5 per cent. ; America, 32.5 per cent. ; France, 5.4 per cent. ; Belgium, 4.6 per cent. ; Austria-Hungary, 2.4 per cent. ; Great Britain, 2.4 per cent. ; and other countries, 6.2 per cent. Of this power, 84 per cent. was employed in iron and steel works, 6 per cent. in collieries, 3 per cent. in electricity works, and 7 per cent. in other directions. In his opinion the reason for the advance in the adoption of the gas engine on the Continent and in America was largely the advent of the electrically-driven reversing rolling mill, which practically dispensed, with steam, and at once opened the way to a large economy by the practical elimination of the boiler range and the utilization of the available gases to the full.

A steel works should not and could not depend safely on a large and regular supply of power where only two or three blast furnaces were in use, as the working of the furnaces would not be sufficiently regular nor the gas sufficiently constant either in quality or quantity. These difficulties could be overcome to a large extent by the introduction of a comparatively inexpensive gas producer plant to act as a stand-by. In such a way it was possible that the fullest use could be made of the gases from a small number of blast furnaces to furnish the necessary power in an adjoining works ; but how far such methods could be applied economically depended in each particular case, on the value and condition of the existing steam raising plant and the cost which would be involved in replacing the steam by gas-driven plant. Steel makers abroad obtained their power, practically speaking, for nothing, while in many British works, almost every horse-power must be developed by the actual utilization of coal in steam boilers.

The question was, how could this coal be used to the greatest advantage ? The time had surely passed when a British steel-maker should hesitate to generate his power by gas engines. Many works now depended successfully on such engines, and it might be taken as a fact that a properly equipped gas engine station, on modern lines, was as trustworthy as any other type of station. It was also true that, horse-power for horse-power, the power could be raised by this method for, say, one-half the coal that was being expended at the present time in the case of boiler firing. Gas engines up to 5,000 h.p. could now be obtained to give out one-horse power for about 1¼ lb. of coal, which coal could be gasified in producers of simple and inexpensive type. In this way, economical development of power should demand careful consideration, even where blast furnace gases were not available.

Gas Producers.

There was, however, another means by which the cost of energy could be further reduced—by the introduction of gas producers coupled with ammonia recovery and by-products plant. The recovery of by-products marked an era in the economies of blast furnace operations, and it equally marked an era in the economy of steel works practice. Such plants had been already installed in several important works which had not the advantage of being connected with blast furnaces. The gas was raised from producers with which an ammonia recovery plant was connected, and from each ton of fuel so gasified, sulphate of ammonia of a gross value equal to, or exceeding, the original cost of the coal was being obtained continually,—probably the nearest approach to "gas for nothing" which would be obtained by any method other than a blast furnace plant. In either process, apart from the cost of the plant itself, the energy in the fuel might be considered a by-product, while continuous rolling mills were being driven direct-coupled to gas engines, and a large part of the auxiliary machinery was being worked electrically from power so generated.

Harold Smith, production engineer for the Canada Foundry Co., Toronto, has accepted a position as assistant superintendent of Mather & Platt's whole plant, at Park Works, Manchester, Eng. Previous to coming to Canada he was in the employ of this latter firm for 10 years, 4 of which were spent in the capacity of shop superintendent of the electrical department. In addition to his recent appointment with the Canada Foundry Co., Mr. Smith was for two and a half years and one year respectively, superintendent of the Montreal Light, Heat & Power Co. repair and manufacturing shops, and that of the Canadian-Crocker-Wheeler Co., St. Catharines, Ont. Mather & Platt have during the last 10 years been rebuilding, re-equipping and reorganizing their whole plant, provision for same having been made by the purchase of 40 acres of land 2½ miles outside Manchester. The firm employ from 1,200 to 1,500 men, and while claiming to be the largest turbine pump manufacturers in Europe, they, in addition, do an extensive business in all manner of fire, hydraulic, electrical, mechanical and textile machinery. Mr. Smith sails for England early in February.

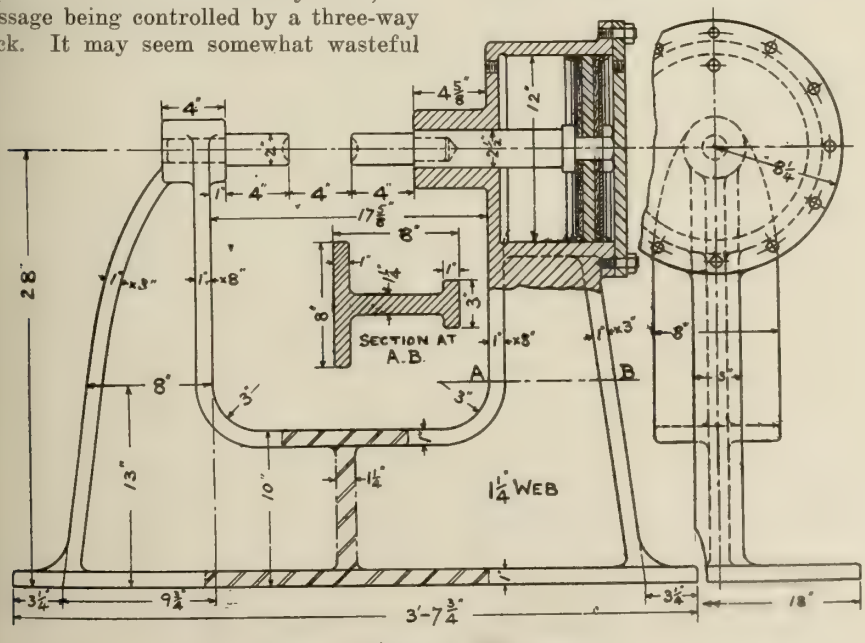
SMALL PNEUMATIC GAP RIVETER.

By J. Harcourt.

THE 18-inch gap riveter here shown was designed for riveting rough, light plate work where a pressure tight joint is not required. It operates under an air pressure of 115 pounds per square inch and is capable of closing rivets up to and including ½ inch diameter. The cylinder and yoke form a single grey iron casting, the stresses in which were kept fairly low in order to secure rigidity when riveting. Thus, under the air pressure above referred to, the maximum fibre stress in the compression flange is about 5,900 pounds per square inch, while in the tension flange it does not rise much above 2,600 pounds. The riveter has a base 18 inches wide, and is bolted down to a light concrete foundation. Air is admitted by a ½-inch pipe to either end of the cylinder, its passage being controlled by a three-way cock. It may seem somewhat wasteful to use air for returning the piston to the beginning of its stroke, but the action is thus made much quicker and more certain than would be the case if a spring were employed for the purpose. Leakage past the piston is prevented by two cup leathers clamped to the ¾-inch steel plate, which forms the main piston, by means of two light follower plates and set screws. The cylinder cover is also made of ¾-inch steel plate and is attached by twelve ⅝-inch studs. A ram, or piston rod, 2½ inches diameter guides the piston and carries the moving rivet snap. There is a slight leakage of air around this ram during the return stroke, but it does not amount to very much and helps to cool off the snaps! It could, of course, be easily eliminated by fitting a leather U collar round the ram at the front end of the cylinder, similar to that used in a hydraulic ram.



Small Pneumatic Gap Riveter.

This riveter is in regular use in one of the largest shops in Canada and was built and installed at an approximate cost of $75.

SNAP GAUGES.

By Chas. Hattenberger.

THE ordinary type of snap limit-gauge offers no means of taking up wear, since it usually consists of a solid drop forged steel body having certain sized openings at each end marked GO or NOT GO. In course of time, these openings wear large and become useless for accurate work. Herewith are shown a number of different types, all of which may be readjusted to correct size when wear has taken place.

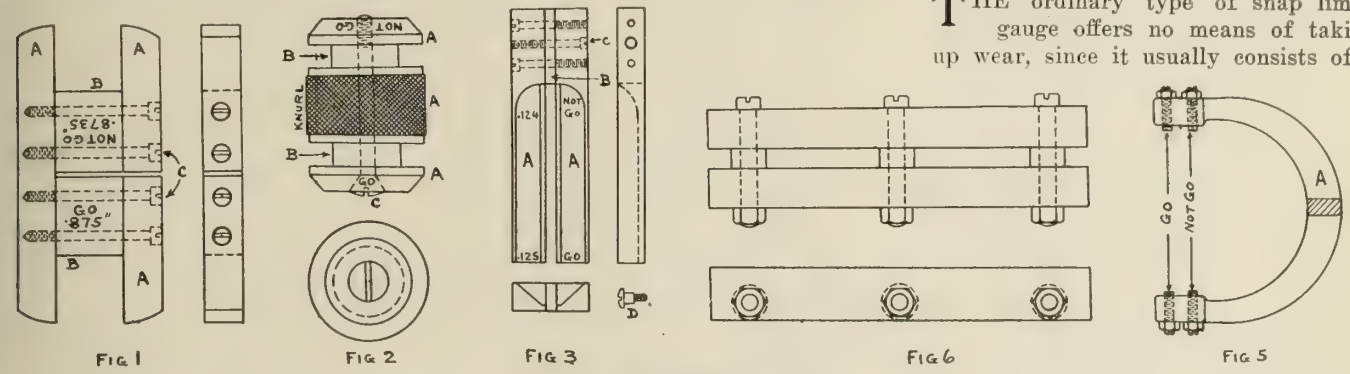


FIG 1 FIG 2 FIG 3 FIG 6 FIG 5

Snap Gauges.

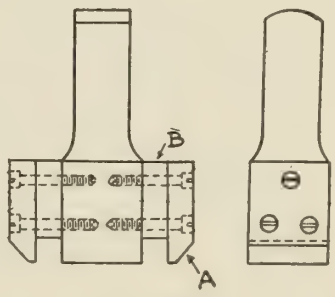

FIG 4

Snap Gauges.

Fig. 1 shows a double ended gauge having jaws, A, of tool steel. These are first milled or planed to size, and then have the screw holes, C, drilled and tapped in them. They are next hardened, after which process it is best to lay them aside for a few weeks, if possible, in order that they may season, and any internal strains be released. They are then ground and lapped straight and affixed to the soft machinery steel size blocks, B, by means of the screws. When wear has taken place it is only

necessary to unscrew the jaws and lap them straight again.

The type of gauge shown in Fig. 2 is very useful for inspecting piston rings.

Fig. 1.—Positive Drive for Miller Arbors.

The jaws, A, are turned up in the lathe, hardened, and then ground and lapped true on their face. The size blocks, B, are of soft machinery steel, while the centre bolt, C, holds all parts together.

Fig. 3 shows a handy type of gauge for inspecting small screws or other articles having a narrow body. (See screw shown at D.) The jaws, A, are made straight and parallel, but the size block, B, is tapered, so that the jaws will be .001 inch wider at the opening than they are at the neck. In order to lighten the gauge the jaws have a bevel milled on them. The screw or other object to be measured is inserted in the opening as far as it will go. If it goes up more than a predetermined distance it is rejected.

The gauge shown in Fig. 4 is constructed on somewhat similar lines to the others shown, but has a handle. The jaws are also wider, being about three times the width of the opening, It forms a convenient gauge for inspecting bar stock, drill rod, etc.

Fig. 5 shows a gauge consisting of a forged yoke, A, and four hardened screws tapped through the ends of the yoke and secured by lock nuts. The outer screws form the GO and the inner screws the NOT GO portion of the gauge. When wear takes place, it is only necessary to screw down on one or other of the screws, first loosening the locknut.

In Fig. 6 is shown a gauging fixture which was used when straightening some small shafts. The latter were 5-16 inch diameter by 5¾ inches long, and were made from 5-16 inch drill rod. After being cut to correct length, they were inserted between the jaws of the gauge. If the shaft did not revolve freely in the opening, which was .3135 inch wide, it was removed and straightened by a raw-hide mallet upon an accurately planed block of cast iron. All parts of this gauge were left soft, except the jaws, which were hardened, ground and lapped on the measuring side.

POSITIVE DRIVE FOR MILLER ARBORS.

By Donald A. Hampson.

WHEN high speed milling cutters came into general use, the heavier cuts which had to be taken in order that they should prove profitable, found out a weak spot in our millers. Many experienced a lack of power under the new conditions, but in our shop the trouble was a slipping of the arbors in the spindles. Though driven in with a lead maul, and further held by draw-in rods, they persisted in turning under these heavier cuts. To remedy the trouble, I had driving heads turned up from bar steel—one of these being seen in Fig. 1.

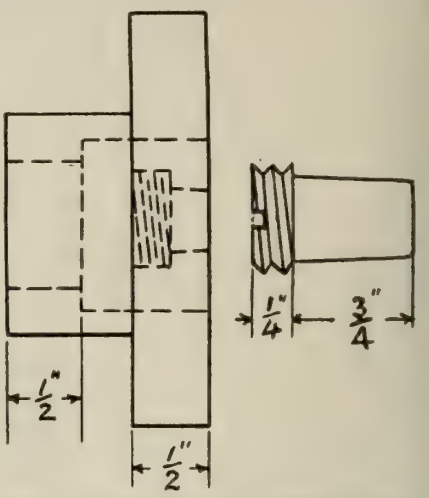

Fig. 2.—Positive Drive for Miller Arbors.

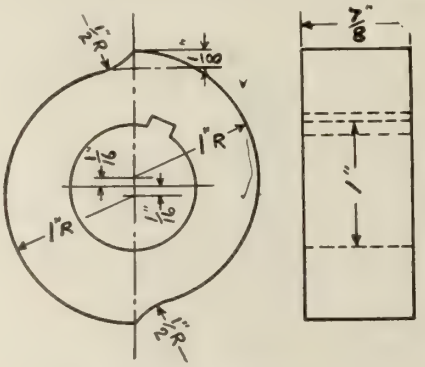
It is threaded to screw upon the nose of the machine spindle and when screwed up quite tight (outside flats for this purpose may be seen), is further locked by two special short, thick screws. The shoulder on every arbor for each machine was flattened on two sides and the driving head for them cut out to fit. Needless to say, no more slipping of arbors was observed after these heads were applied. All later millers of course have such a device as an integral part.

Fig. 2 gives a few dimensions that may be of interest, and also shows one of the screws. It will be noticed that everything is removable, in case some job with limited clearance at that end calls for all the room obtainable. An expenditure for work of this kind is justifiable, not only on account of the direct results obtained, but also from an ethical standpoint, for anything that discourages sledgehammer heroic methods, on fittings that are not to become a permanent assembly, is in line with good practice.

READER, WHAT DO YOU KNOW?

Among readers of Canadian Machinery there is a clearly defined sincerity of desire to know how each overcomes the daily tasks of the machine, pattern and blacksmith shops, the foundry and boiler shops. It is believed that your methods and devices, while good, may be improved, and thereby made more valuable if you publish them, so that other brains may work on them. We will provide the setting and pay you for the material. When your fellow tradesman puts the superstructure on your foundation, we pay him and pass the "kink" on to you, free. Get into the game.



Making Cams for Relieving Attachment.

MAKING CAMS FOR RELIEVING ATTACHMENT.

By A. D. Campbell.

ON page 24 of the January issue of Canadian Machinery there was shown an attachment for relieving taps, etc., in a 14-inch lathe, and it is hoped that the following description, of how the cams in such an attachment are made, may prove of interest.

The blank cam is mounted on a suitable arbor and fixed securely in a universal dividing head. The latter is fastened at right angles to the travel of a milling machine table. The indexing arrangement is then set for 250 divisions, because in this particular case the throw

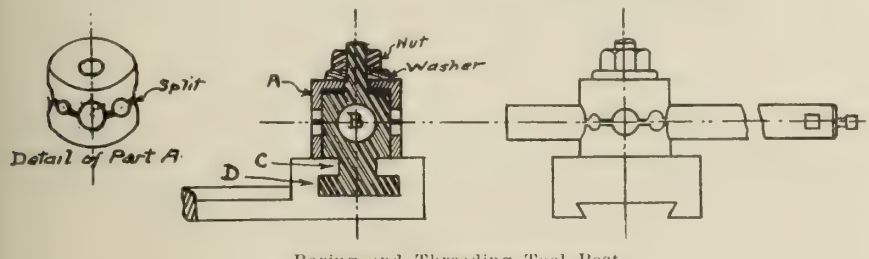
of the cam is ⅛ inch or .125 and there are two lobes. The combined throw is, therefore, .250 inch. The diameter of the cam roller is 1 inch, so we insert a 1 inch spiral end mill in the spindle of the milling machine and all is ready to carry out the job. Touch the cutter on the work and set the graduated collar on the knee elevating screw at the zero mark, Move the dividing-head index pin through one division and raise the knee .001 inch. Then move the index another division and raise knee another .001 inch, and so on until the index pin has moved through 125 divisions, during which time the knee will have been raised .125 inch and the work will have moved through 180 degs. Next, drop the knee back to the zero mark and repeat the operation. If the cam is to be very accurate, a second cut, of about .005 inch, is advisable; it will then be hardly necessary to use a file, as the finish on the job will be quite smooth enough as it comes from the miller.

This method is applicable to a large variety of cams and is much quicker and more accurate than laying them out and filing to lines.

BORING AND THREADING TOOL POST.

By A. Leonard Marshall.

THE boring and threading tool post shown herewith is made of mild steel and will be found very handy for use on an engine lathe, as it has the advantage of always being ready for any one of four different sizes of bar. The tool post proper has a hole, B, bored through it slightly bigger than the largest bar to be used. The shell A is made a loose fit on this post and is drilled for the four different sizes of bar. It is then cut in two horizontally through the centre of the holes. If the parts marked, C and D, are made circular in section, the boring bar may be set to any angle. By tightening the nut on the top, the whole thing is clamped at one operation.



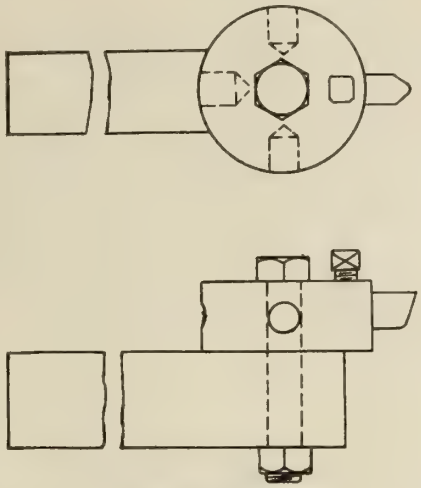
Boring and Threading Tool Post.

Editor's Note.—We publish the above as sent us; but we see no reason why the shell A should not be made in cast iron, as it would be somewhat expensive to make in mild steel.

A RADIAL PLANER TOOL.

By H. Fozard.

THE accompanying sketch shows a very useful tool for the planer or shaper. It may be used for work requiring long half-round grooves or for forming half bearings for journals in engine beds, etc. By inserting a long bar in the holes around the head, the tool may be gradualy rotated, thus describing an arc. The bolt is adjusted to allow of the tool being moved round with a slight pressure.



A Radial Planer Tool.

MACHINE TOOL AND ENGINEERING ASSOCIATION.

THE annual general meeting of the Machine Tool and Engineering Association was held at Manchester, England, recently. The chairman, Mr. J. Taylor Peddie, of Messrs. Vickers, in the course of his address urged the importance of organization as a force in the industrial world. An organization was not successfully created that did not have within it departmental organization, or what was known as the unit system, and no organization could be considered to be successfully organized that carried centralization to such an extent as to devitalize the departmental organizations below. It seemed to him that their energies should be concentrated in the direction of improving the efficiency of existing organizations; the association had been formed primarily for this purpose, and the need for it was only too apparent. Present economic conditions necessitated this policy. Rigid economies must be effected in all departments, and this could be done by increasing efficiency through combination or any other method that might present itself to those responsible for the management of industry. He pointed out that as cost of production decreased, wages increased; and it should be borne in mind that costs of production continuously decreased, hence the reason why industry remained active.

Since the statutory meeting of the association in March, 43 additional firms had joined, bringing the total membership up to 80. During the year several members had applied to the association for permission to exhibit at various exhibitions, and permission had been given or refused according to the circumstances of each case. The Home Office had also been in direct communication with the association with respect to the question of adequately guarding gear wheels of machines and had pointed out that foreign machine tool manufacturers supplied their machines adequately guarded, and that the cost of doing so at the time of manufacture was a relatively small item as compared with the subsequent cost of conversion. The Home Office further stated that in many cases British firms had lost orders owing to the want of adequately guarded gear wheels.

With reference to the Machine Tool Exhibition to be held in October at Olympia, the prospects were eminently satisfactory. Of an available space value of $67,500, considerably over $40,000 had already been let definitely. A considerable portion of the remaining space was also at present under option, and this fact strengthened the hands of the Exhibition Committee in entering upon the necessary expenditure to provide adequate publicity so as to ensure a large attendance of those interested in improved methods of production, and also engineering buyers.

AMERICAN BOILER MANUFACTURERS' CONVENTION, 1912.

The 24th annual convention of the American Boiler Manufacturers' Association, together with its Associate Members and the Supplymen's Association, will be held in New Orleans, La., March 12, 13, 14 and 15, 1912. Some important papers are to be presented, and other business discussed, which will be of interest to all manufacturers and supply houses in the United States and Canada, engaged in the boiler and tank industry. An extensive programme of entertainment has been arranged, and a large attendance is expected.

Mechanical Drawing and Sketching for Machinists

By B. P.

A Series of Progressive Lessons Designed to Familiarize Engineers With the Use of the Apparatus Necessary to Make Simple Drawings, to Encourage Them to Realize How Important a Factor it is of Their Equipment, as Well as Being a Profitable Pastime.

Small Machine Vise.

THE first example shown this month is a small machine vise suitable for holding work on the table of a drilling machine, planer or shaper. As may be seen in Fig. 1, the casting A has a hole bored in it at one end, in which the swivelling jaw B is fitted, being kept in place by a circular plate and ¾ inch screw. The object of making the jaw to swivel is to enable it to grip non-parallel faces, but this is a feature not often met with, it being lar nut which bears on the inside of casting A and revolves with the screw. It is threaded on the latter and secured by a taper pin. The head of the screw is enlarged to 2 inches diameter; two ⅞ inch holes being drilled through it at right angles for insertion of a "tommy bar" when closing or opening the jaws. The vise is secured to the machine by ⅞ inch T-headed bolts fixed in the slots of the table and passing through the slots in the base of the vise.

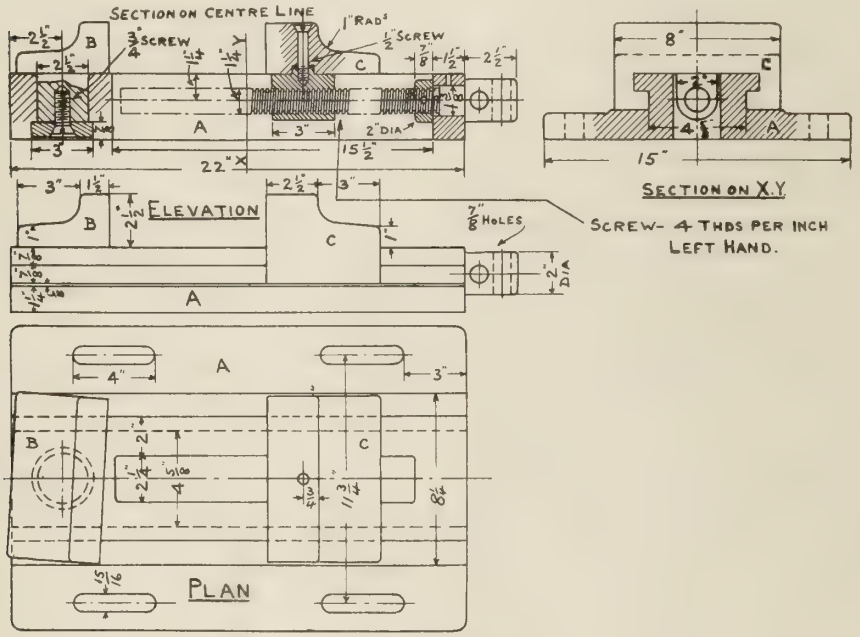


Fig. 1.—Drawing and Sketching.

more common to make the jaw B solid with the base A and to pack up the non-parellel side of the work with wooden or metal wedges. In the present example it will be noticed that the sliding jaw C, is not solid with the nut, but is attached to the latter by a ½ inch screw having a countersunk head. The shear is taken off the screw by a strip or tongue on the nut which fits into a recess on the jaw. The main screw is 1¼ inch diameter and has 4 threads per inch. It is made left-handed in order that the moving jaw, C, may advance on the work when the screw is turned in the usual right-handed direction, in the same direction as that in which the hands of a clock move. The thrust is taken by a circu-

In the plan view, the jaw B is seen swivelled through a slight angle for the purpose already explained. Each part is similarly lettered in the various views and the student should have no difficulty in finishing the drawing and adding an end view. Several dimensions have been purposely omitted, and the screw is, of course, not shown completely. Draw to a scale of 4 inches to the foot. The jaws, main nut and base are of cast-steel, and the screw of forged steel.

Exercise.—Draw each part of the above vise separately to a scale of 6 inches to the foot, with the exception of the base A which may be drawn ¼ size. There are nine parts in all, excluding the taper pin.

Ratchet Stud Driver.

Fig. 2 shows an all-steel ratchet stud driver, fully assembled. The socket shown is tapped to suit a ⅞ inch stud, several similar sockets accompanying each rachet and each taking a different size of stud. In the upper view the thread appears to extend only half way through the socket; but the object of so drawing it is merely to show the length of the threaded portion of the handle, by means of which the socket is inserted or removed. The 8 teeth in the circumference of the socket are ¼ inch wide and are cut in a milling machine; hence their segmental appearance in section. The radius of the bottom of the tooth is not stated on the drawing, as it is unimportant and depends solely on the diameter of the milling cutter used. The socket is prevented from falling out by the ¼ inch set screw, the point of which engages in a circular groove. This screw should be located ½ inch above the bottom of socket. All other necessary dimensions are clearly shown, with the exception of the size of the coil spring which keeps the pawl in place. This is of steel, and has six coils whose outside diameter is ½ inch and inside diameter 13-32 inch. The head of the pawl is knurled to facilitate drawing back against the pressure of the spring when removing the socket. The handle in the upper view is not shown quite accurately; we leave it to the student's ingenuity to discover what is amiss. Draw to half size and give an end

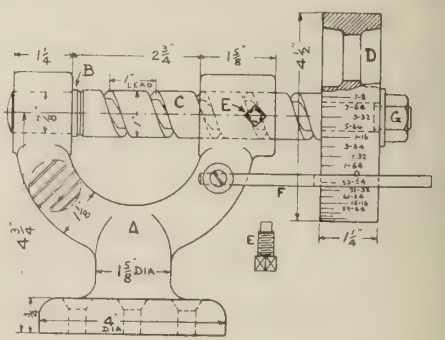

Fig. 3.—Drawing and Sketching.

view, looking at the rachet end.

Exercise:—Draw to full size, the socket, pawl and spring, giving all necessary views and dimensions of each.

Twelfth of a Series of an Instruction Course

Gauging Device.

We now come to Fig. 3 which shows a device for gauging the size of twist drills, reamers or similar tools. As only one view is given and several dimensions are omitted, it will serve admirably to test the progress already made by the student, while at the same time giving him an opportunity to prove his ability as a designer. It will first of all be necessary to get a clear idea of the working and construction of the gauge, for which purpose the following is extracted from a description which appeared in Canadian Machinery of December last:—

"The gauge consists of a cast-iron stand A, having two arms, one of which is drilled ⅞ inch diameter to take the anvil B, which is pressed in. The other arm is not screwed, but is bored out plain to take the measuring screw C, 1 inch diameter. The lead of this screw equals one thread per inch, the groove being ¼ inch wide and 3-16 inch deep. One end of the screw is turned down to fit the hub of the cast-iron wheel D. The latter has four spokes and is turned to 4½ inches diameter. The circumference is then graduated in the milling machine into sixty-four parts, which are marked from zero to 63-64. A small screw E fits into the groove of the measuring screw and acts as a nut.

Readings are taken by means of the straight edge F, which is made of round cold-rolled stock, and is filed flat for a portion of its length, in order that it may be brought close up against the wheel and clear readings obtained. Its round end is clamped in a boss which projects from the casting A. When the end of the screw C is touching the anvil B, the wheel must be adjusted on its spindle so that the zero mark comes in line with the top of the straight-edge F. It can then be secured permanently in position by the nut G. The face of the anvil and end of the screw should be case-hardened with cyanide, and the base of A drilled for three holding-down screws.

Readings are obtained by inserting the drill, or other tool to be measured, between the end of the screw and the anvil, and reading off the size on the wheel at the straight-edge. If the drill is larger than 1 inch, a number, equal to the number of revolutions of the wheel from zero, must be added to the reading. Thus, in gauging a 1¼ inch drill, the wheel will make one complete turn and stop at the ¼ mark. Similarly for a 2¼ inch drill, the wheel will make two and a quarter turns. In practice the toolkeeper does not need to keep track of the number of revolutions. The fractional reading is all he needs, since his eye enables him to tell whether the reading is for a ¼, 1¼ or 2¼ drill.

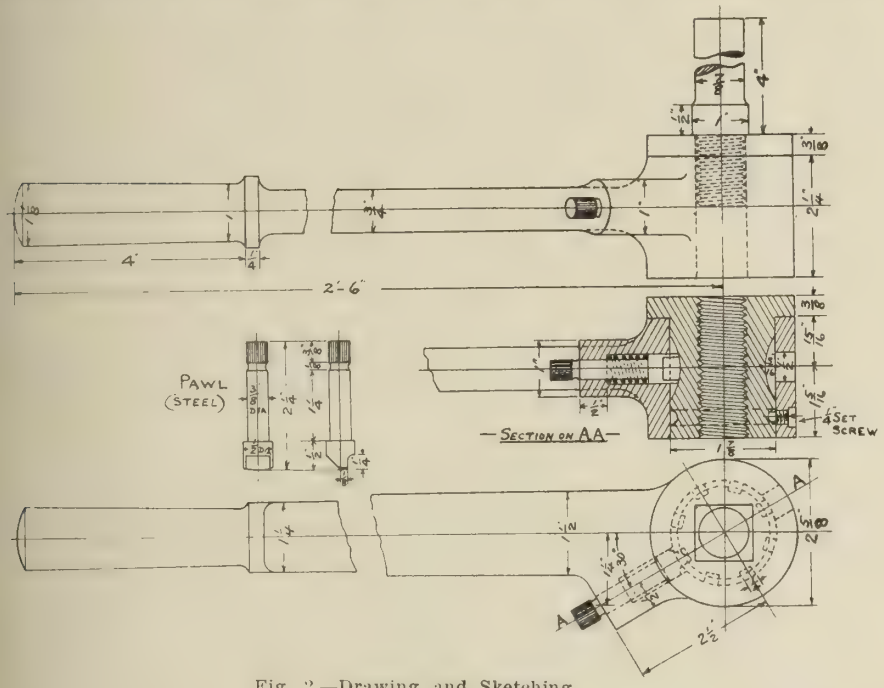

Fig. 2.—Drawing and Sketching.

In drawing this gauge, the bosses through which the screw and anvil pass should be made 1¾ inches in diameter. The straight edge F is made from ¼ inch cold rolled steel and should extend 1⅜ inches beyond the outer edge of the wheel in order that drills up to 2½ inches in diameter may be gauged. The wheel might with advantage be brought somewhat closer in—say ½ inch from the boss—when screw is in the position shown. To obtain the graduation marks on the rim of the wheel, an end view of the latter is drawn; the circumference is then divided into 64 parts and by means of the tee square, the points of division are then projected across to the other view. The hub of the wheel is 1¼ inch diameter and has a ⅝ inch hole in it. G is a ½ inch nut, while the small set screw E is ⅜ inch diameter and is screwed 16 threads per inch. Its point is turned down to ¼ inch diameter to fit the groove in the screw. It will be remembered that full instructions for correctly drawing such a screw thread were given in our eighth lesson, appearing in September last. Notice in the present case, that though the pitch (or lead) of the screw is 1 inch, the width of the thread and the space are not both ½ inch, as is generally the case. Here the width of the thread is ¾ inch, while the space is only ¼ inch wide and 3-16 inch deep.

The gauge is fastened to a bench by three countersunk headed screws ⅜ inch diameter. These are equally spaced in a circle, and care must be taken not to locate one of them below one of the arms of casting A, as it would then be impossible to insert the screw, if the latter were reasonably long. The straight edge F is held in a boss cast on A by a clamping screw; the design of this, as of several other points being left to the student's judgment. Draw to a scale of 6 inches to one foot and make a complete drawing, showing three views.

Personal

Mr. Baker, manager of the **Hamilton Carharrt Co., Toronto branch**, has resigned, and **C. F. Fell**, from the Detroit office has been appointed to succeed him.

* * *

W. J. Usher has been appointed manager of the Garlock Packing Co.'s new Winnipeg branch, and associated with him are **B. E. Dalzell** and **E. C. Medland.**

* * *

Arthur R. Bell has received the appointment of manager of the Garlock Packing Co.'s new branch at Vancouver, and will have as assistant, **Geo. Cook.**

* * *

Hugh Jackson, treasurer of the Positive Clutch & Pulley Co., has resigned his position to become cashier of the Canadian Fairbanks-Morse Co., at Calgary.

* * *

Mr. J. F. I. Thomas, who superintended the erection of the Hydro-Electric Plant for the city of Winnipeg, as representative of Vickers, Ltd., is now permanently located in Montreal, where he will look after the electrical end of Vickers, Ltd., business throughout the Dominion of Canada.

The New Foundry of Beauchemin & Fils, Ltd., Sorel, Que.

By L. G. Dennison, B.A., B.S.C.*

Steel Castings Now Fill so Large a Place in the Design and Constructional Detail of Mechanical Engineering Products That it is Little Wonder There Should Follow the Establishment and Equipment of Foundries, in Localities More or Less Central, to Accommodate the Prompt Requirements of the Industries Affected. The Plant of Beauchemin & Fils Betokens Not Only a District Demand, But Also a Highly Commendable and Tangible Expression of Enterprise, Worthy of Emulation.

THE rise and progress of the Canadian steel industry during the immediate past has been nothing short of phenomenal, and although the year 1911 has witnessed a market glutted with American pig and American ore, the steel products of our home manufacturers have been finding an ever increasing market. Evidence of this fact is to be found in the completion of the large steel foundry addition made by Beauchemin & Fils, Ltd., Sorel, Que. This firm, established in 1855, incorporated in 1902, and engaged in manufacturing agricultural machinery, launched into the manufacture of steel castings about two years ago. Their product has commanded such a growing market that new shops capable of a 3½ times increase of output have been found essential. Chrome, manganese, nickel and special carbon-steels are made by the converter process, as also electrical metal, and special attention is given to marine and railroad requirements. A large dredge drum, weighing 8,000 lbs. was made recently. The capacity output is now 25 tons per day, as against 10 tons per day previous to the extensions taking place.

*Associate Editor, Montreal.

The Buildings.

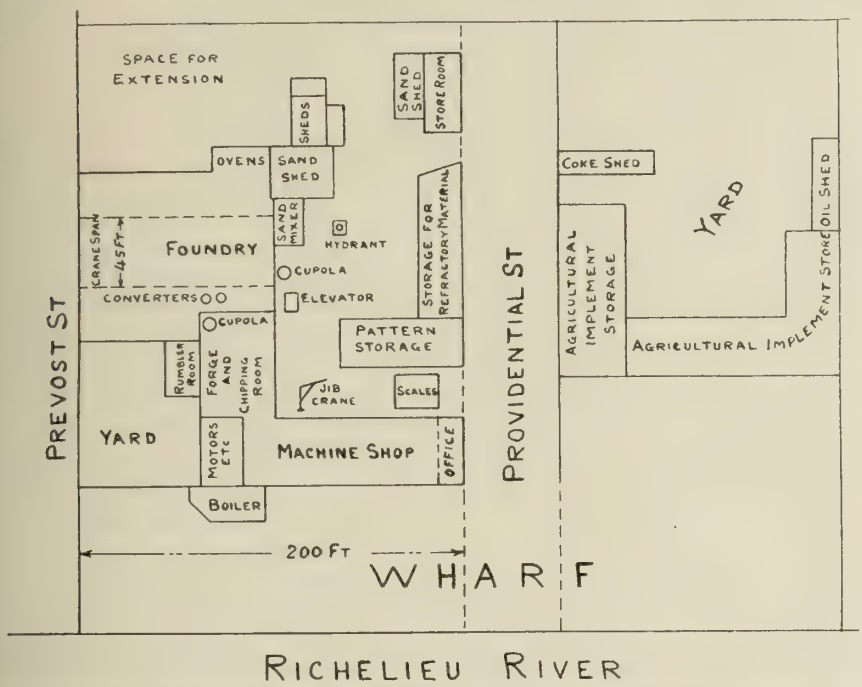
The buildings occupy a ground area of about 112,000 square feet and consist of two blocks, on opposite sides of the street, of sizes 320 x 200 and 320 x 150 feet. Both properties stretch to the river front, thus affording excellent shipping facilities. The foundry extension of steel and concrete gives this section 85 x 100 feet of floor space. The height at the centre is 35 feet and under the wings 22 feet. The roof is of corrugated steel sheets. The machine shop, built of brick and showing the smoke and weather effects of more than half a century, covers an area of 200 x 40 feet. The power equipment, motors and compressers are at one end of the machine shop. The fettling shop is located as shown on ground plan. The foundry and machine shop are both well provided with windows and a well distributed equipment of incandescent lamps furnishes ample artificial light.

The Foundry.

The main foundry floor is served by a 10-ton Whiting crane of 45 feet span, and equipped with 3 C. G. E. 220-volt A. C. motors of 25, 15 and 7½ h.p. A 10-ton Baillot cupola and a 25-ton Whiting cupola are placed near one end, as indicated by circles. These supply two 2-ton Stoughton converters; the usual arrangement of swinging channels being provided. A motor-driven one ton elevator in the yard runs to the charging floor 25 feet from the ground. The interior cupola, being situated in the wing where the building is low, passes through the roof, and the charging floor, suitably enclosed, is built on top of the latter.

* New Foundry and Engineering Works of Beauchemin & Fils, Ltd., Sorel, P. Q.

There are two drying ovens of dimensions 30 x 10 x 8 feet, built in the corner under the wing and heated with coal fires. In connection with these there is installed a rail truck system, arranged for crane loading. An annealing furnace of the usual type, built and installed by the company, and of inside dimensions 10 x 8 x 4 feet, is included in the equipment; also a series of ladles of



Ground Plan of New Foundry and Engineering Works of Beauchemin & Fils, Sorel, P.Q.

capacity from five tons down and a complete modern set of adjustable iron moulding boxes. The foundry gives employment to one hundred men.

The Machine Shop.

The machine shop, 110 x 40 feet, has an equipment consisting of lathes, planers, drills, shapers, millers, saws and emery wheels. Forty men are employed in this department. The pattern and wood working shop, employing seven men, is above the machine shop. The tumbler room and chipping or fettling room is located between the two, as shown on the ground plan. A Davis-Bournonville oxy-acetylene welding outfit is installed in the latter.

Power Equipment and General.

Power at 220 volts and 25 cycles is obtained from the Sorel Electric Co., and is used also for lighting purposes. The motors are Canadian Westinghouse and Canadian General Electric. A 75 h.p. motor is used for the main drive of the machine shop, and another of equal power drives a Sturtevant blower, which serves the two cupolas. A 50 h.p. motor serves the two converters. The various air operated appliances and tools are served by a Chicago Pneumatic Tool Co., compressor driven by a 25 h.p. motor.

There was a considerable increase of both working and invested capital when operations recently commenced on the larger scale, and the future holds out the brightest prospects. The destinies of the enterprise are under the able direction of the following Board: Alfred Beauchemin, President and General Manager; V. E. Beauchemin, Vice-President; L. Phillipe Tremblay, Secretary-Treasurer, and Alphonse Beauchemin, Director. The works superintendent is J. M. Ryan, of Pittsburg, late with the Montreal Steel Works, the Pittsburg Steel Foundry Co., and the Mesta Machine Co. This foundry is located in an important ship-building centre, and with a wharf and harbor on its own property is in a favorable position for shipping by water route to all the great lake ports, and, therefore, the interior of the Dominion generally.

HARDENING AND TEMPERING CARBON-STEEL TOOLS.

II.

By Frank Walker.

THE tool, after undergoing the previously mentioned process, will be found much too hard and, therefore, too brittle for practical use, and must as a consequence be subjected to the heat treatment known as tempering, in order to modify these conditions to suit actual requirements.

The Process of Tempering.

Tempering is a partial annealing or softening of the hardened steel, by which means it is possible to restore some of its toughness or ability to withstand shocks and strains, and at the same time retain sufficient hardness to carry a good cutting edge. The process of tempering also relieves to a great extent the internal stresses set up in the steel by hardening. A little thought will show that it is practically impossible to heat or cool a piece of steel uniformly through to its centre, as the outside or skin of the piece will be sensibly hotter than the core when it is removed from the furnace, and will be cooled for an appreciable time before the core when quenching takes place, thereby causing unequal contraction strains which vary in proportion to the size of the piece, the heat at which it is quenched and the temperature of the quenching bath.

The process of tempering is an extremely delicate one. Quenching, as has been explained, "traps" the hardening carbon in combination with the ferrite, and a re-application of heat at a comparatively low temperature will release this hardening carbon and cause the steel to resume its normal or annealed state. In carbon-tool-steels, this change commences when the piece under treatment reaches a temperature of from 390 to 400 degs. Fah., and continues till 700 degs. is reached, at which point the whole carbon-content will have resumed its original form, and the steel its least degree of hardness. In this range of about 300 degs., it is possible, by careful manipulation, to obtain and fix by quenching any degree of hardness required and which the quality of the steel will carry. This degree of hardness can be very accurately determined by the color which the piece assumes as the heat increases.

Determination of Degree of Hardness.

When the piece is first withdrawn from the quenching bath its hardened portions will present a silvery grey appearance, and before tempering they must be polished with emery or rubbing stone in order that the changes of color may be seen more distinctly. If the piece be now heated to 420 degs. Fah. a faint tinge of yellow will appear on the polished surface, and which will gradually deepen as the heat is increased; changing to a straw color at 460 degs., brown at 500, purple at 540, blue at at 560, and a very dark blue merging into black at 610 degs. There is as low as is necessary to bring the hardness of any tool for practical purposes. These changes of color are caused by a film of oxide forming on the polished surface, which film thickens with the increasing exposure to the heat.

Methods of Tempering.

There are many methods of tempering, each particular class of tool requiring a different treatment. For lathe tools, chisels, etc., the "back-heat" method is the one most generally used by tool-smiths and is a very efficient one when properly carried out. By

this process a tool may be hardened and tempered by once heating. The tool to be treated must be treated in such a manner that only the point or cutting edge reaches the "decalescence" point; the heat graduating back into its other extremity, the heft or tool butt, and not rising above 350 degs. It should then be quenched carefully in the manner before explained, submerging it for about 1½ inches from the point, and holding it in the water till the heat of the unsubmerged portion just above the water line has been reduced by radiation to a dull glow—about 800 degs. Fah. Next remove it from the bath and polish quickly and carefully with a piece of rubbing stone, then, standing close to the quenching bath, hold the tool in such a manner that the light is reflected from this polished surface. In a few moments the temper color will begin to show and gradually extend towards the edge, deepening from behind as it travels. When the cutting edge has assumed the shade which represents the degree of hardness required, dip the tool quickly in the water and quench completely. This is known as "fixing the color."

The foregoing may seem a very simple process, yet nevertheless, it is one which requires great skill and care. The heating, especially, must be very accurately judged so that there is only sufficient back-heat left after the first dip to draw the temper to the required degree, for, if this is not done, great waste of time and material will result. I dare say some of my readers have seen the tool-smith, when tempering, after waiting some little time for the color to run, hold the tool in the flame over the forge:—He has miscalculated his back-heat and has not sufficient to draw the temper on again. They may have had a tool which snapped-off, about an inch or so from the point, at the first cut; in this case, there has been too much back-heat and the steel has been strained when quenching in the final dip. In a tool properly tempered by this method, the hardness should graduate back from the cutting edge, the heft or unforged portion remaining in its original annealed condition.

The back-heat process should be used only with lathe and planer tools, flat drills, chipping chisels, etc.; in the tempering of taps, reamers, twist-drills, etc., different means must be employed. It should be borne in mind that the shanks of such tools as these also require to be tempered, but must be let down to a much lower degree of hardness than the cutting portions, and this can be accurately and safely accomplished by taking advantage of another little-known characteristic of carbon steel.

Time a Factor in Tempering.

It has been proved that temperature is not the sole governing factor in tempering, but that time must also be taken into account, and careful experiments have shown that it is possible to obtain a dark blue temper color on a piece of hardened steel either by exposing it to 420 degs. Fah. for 4 minutes or to 600 deg. for 1 minute. As a consequence, if, instead of a fire, we use, for reheating, an oil bath maintained at a constant temperature of 420 degs. Fah.—a good-bodied animal oil is best for this purpose—we can then obtain and fix by quenching in cold water any required temper color, by holding the tool in the heated oil for a longer or shorter period:—For instance, the cutting edges of a tap or reamer may be drawn and fixed at a straw color and the shank afterwards drawn to a blue, by holding it,—the shank,—in the oil for a longer period. If this be carefully done, the two temper colors will be found to merge in the last half-inch from the bottom of the shank.

Re-Heating by Oilbath.

The oil-bath for re-heating purposes has many advantages, but perhaps the greatest is the possibility of securing almost absolute uniformity of temperature throughout the whole bath, and if a good lard oil be used, a temperature as high as 520 degs. Fah. may be safely maintained. For tempering threading dies and tools of that shape, polish both sides after hardening, and draw to the temper color by laying them on a flat plate heated to a dull red,—about 1,150 degs. Fah.—turning them over frequently so that both sides attain the same color. Fix by quenching as before.

General Observations.

In this article, the writer has endeavored to explain the methods of dealing with the requirements of the small jobbing or general machine shop. For dealing with milling machine cutters, forming and stamping dies and punches, and similar tools, a complete hardening and tempering plant should be installed, forming a separate department, controlled by an expert. In all cases, the tool-smith must be governed by his own judgment with regard to the size, shape and requirements of the tool being treated. Absolute accuracy in the heating is essential, "near enough" methods will not do, for a variation of 20 degrees in the heating of a good brand of carbon-steel will make all the difference between failure and success. These two points must be borne in mind.—Firstly, the tool to be hardened must always be drawn from the furnace on a rising heat and should never be allowed to "soak," that is, be held at a constant temperature for any length of time. In order to insure this, the heat of the furnace or muffle should be kept at least 300 degs. above the "decalescence" point of the steel being treated. Secondly, the tool after forging should be allowed to cool down to about 180 or 200 degs. in a warm, dry place before it is heated up for hardening.

In conclusion, a few remarks on forging may not be out of place. Heat in a clean, bright fire of generous dimensions,—charcoal does best for the former,—and use just sufficient blast to keep the fire brisk. Forge at as low a heat as the steel will take to kindly. Work the piece from back to edge, uniformly, and remember that continued hammering, at very low heats, improves the quality of sound carbon-steel. Lastly, never allow the heat to "soak," for "soaking" is as detrimental to good forging as it is to good hardening.

INDUSTRIAL ACCIDENTS.

There were 82 fatal and 194 non-fatal accidents to work people recorded by the Department of Labor during December, 1911. This shows a slight decrease compared with the preceding month, and is much less than in the corresponding month last year. In November there were 286 accidents, fatal and non-fatal, to individual workmen, and in December, 1910, there were 351 accidents. The chief disasters during the month were the suffocating of three miners at Middlesboro, B.C., in a chute of a mine, and an explosion at a powder factory in Departure Bay, Vancouver, B. C., in which three men were killed. There were eleven killed in the railway service, and fourteen in mining. The largest number of non-fatal accidents occurred in the metal trades, in which forty-two were injured. Nine men were killed and thirty-one were injured in the building trades, an unusually high number for the month of December. There were twenty-six non-fatal accidents in the railway service.

Electro galvanizing has proved to be a very satisfactory protection to iron and steel from rust. It has not been found a competitor of hot-galvanizing to any extent, but has replaced other metal coatings such as nickel and copper. As a protection against rust, however, it has been found far superior to these metals.

ELECTRICITY FOR ROLLING MILLS*

By C. Antony Ablett.

IN introducing the subject, the author observed that the power required to drive a rolling mill generally varied rapidly between wide limits, while in order that power should be generated cheaply, the demand made on the generating plant should be maintained steadily at the full capacity of that plant. To ensure that the working costs of a rolling mill should be low, means must be found for reducing the fluctuations in the power required to drive the mill, care being taken in doing this, that the capital cost of the plant was not unduly increased, nor was the possible output reduced. Any reduction of the possible output was equivalent to an increase in the working cost, as the capital charges per ton were increased.

Variation of Power Feature.

The variations in power were reduced by employing a flywheel in conjunction with the electric motor used to drive the rolling mill, and by providing some device for reducing the speed of the motor and flywheel, so as to enable the flywheel to give out some of its stored energy when the demand for power was great, thus reducing the amount of power which had to be furnished by the motor. When the demand was small, the motor would speed up the flywheel, thereby replacing its stored energy ; this increased the power which the motor had to supply when the demand made by the mill was small, and therefore reduced the total variation in power.

Apart from large reversing rolling mills, the largest variations in power occurred in tinplate and sheet mills. With merchant mills and bar mills, the variations in power were less, while in the ordinary looping mill for rolling wire rod, where the rod might be in six pairs of rolls at once, and where a fresh rod was entered while the previous one was still in the rolls, the power required to drive the mill did not vary much. A special case was that of a tire mill, where the variations in power were considerable, but where the power demand remained pretty steady for nearly a minute, so that a flywheel would not prove of much benefit in reducing the fluctuations in power unless it were very heavy indeed.

The stored energy of the flywheel varied as the square of the speed at which it was running, so that if a flywheel were used in conjunction with this motor it would only give up 4 per cent. of its stored energy as the power increased from light load to the full power of the motor. The rolling mill might require during a pass, a power equivalent to four times the normal full-load power of the motor for a few seconds; commercial motors would not give more than twice the normal full-load power for a few seconds without being liable to injury, and to prevent this, the circuit breaker was usually set to open at the current corresponding to that power. The flywheel, therefore, had to furnish the power which was in excess of that which the motor could give. In the case considered, the motor would fall perhaps 5 or 6 per cent. in speed when the power increased from light load to double full-load power, so that the flywheel would give up only 10 or 12 per cent. of its stored energy. The flywheel, therefore, would have to be abnormally heavy, or else if a flywheel of a weight within the bounds of commercial possibility were adopted, the combination would be unable to cope with this demand for power, and the motor power would increase until the circuit breaker opened. It was, therefore necessary artificially to increase the fall in speed of the motor as the power which it had to give increased. If the speed fell by, say, 10 per cent. as the power increased from zero to full load, and, say, by 22 per cent. as the power increased to the double full-load power, the flywheel would have given up 39 per cent. of the stored energy by the time that the motor was giving double its normal full-load power, instead of from 10 to 12 per cent. A flywheel, therefore, of moderate weight, would materially assist the motor in overcoming heavy demands for power which lasted for a short time only.

In practice, the maximum power given by the motor would seldom be so much as double the normal power, nor would the motor power sink to zero, as even when nothing was being rolled, the motor would still have to provide the power for overcoming the friction of the mill, which was considerable. There were two devices for artificially increasing the fall in speed of the motor as the power demand increased. These were commonly spoken of as (1) the permanent-slip regulator, and (2) the automatic-slip regulator; but it would be more correct to call them (1) the continuous-slip regulator and (2) the intermittent slip-regulator.

The Continuous-slip Regulator.

In the case of the direct-current motor the continuous-slip regulator consisted of an ordinary compound winding provided for the field-poles, while the intermittent-slip regulator consisted of a system of relays which successively short-circuited resistances in series with the shunt field winding, thus increasing the field and causing the speed to fall when the power had reached a certain predetermined point. In the case of the three-phase motor, the continuous-slip regulator consisted of a resistance, liquid or metallic, permanently inserted in the rotor circuit, while the intermittent-slip regulator might be either a liquid resistance, the moving plates of which are controlled by a motor relay, so that the plates were raised and the rotor resistance increased when the current had reached a predetermined point, or a metallic resistance which had its various sections short-circuited by a series of relays so arranged that the relays cut the resistance into the rotor circuit when the current had reached the predetermined limit.

For the sake of simplicity it was assumed that the fall in speed of the motor or slip below no-load speed was proportional to the power which the motor was giving. Within the limits of fall in speed or slip of the motor, it could be assumed that the stored energy given up by the flywheel was proportional to the slip, without involving any large error, therefore, the power given by the flywheel was proportional to the rate of change of the slip or to the rate of change of the motor power. Thus, if a sudden increase of load was imposed on the motor and flywheel by placing a bar between the rolls, and a curve was constructed showing the increase of motor power with the time, this curve would be a logarithm curve; while if the power required by the mill suddenly decreased owing to the bar leaving the rolls, the motor power decreased also, according to a logarithm curve. The curves showing the rise and fall in speed of the motor and flywheel were also corresponding logarithm curves. After the bar left the rolls, the power which the motor gave, while decreasing to the value corresponding to the friction, went to increase the speed of the flywheel, and so replaced its stored energy. These curves were quite analogous to those for the heating and cooling of electrical machinery, the power of the motor, however, rose to practically its full value in a few seconds, while the temperature of an electrical machine took a number of hours to reach approximately its full value.

Intermittent-slip Regulator.

One type of intermittent-slip regulator suitable for direct-current motors consisted of a small motor relay to set in operation a number of relays which successively connected resistances in parallel with the resistance placed in series with the shunt field of the motor. The field of the motor relays was excited by the main current passing through the mill motor armature. If the mill motor was small the main current passed through this field, but if the main current was too big, the field was placed across a shunt in the mill motor circuit.

*Abstract of paper read before the Institution of Electrical Engineers, London, Eng.

The action of the intermittent-slip regulator was very different from that of the continuous-slip regulator. It came into action when the power given by the motor attained a certain value, and when this point was reached a very slight increase in power indeed would cause the intermittent-slip regulator to act to its fullest extent.

Theoretically speaking, therefore, the power could be maintained at its average value with a deviation of perhaps less than 1 per cent., so that the power curve was practically a straight line, and did not rise and fall in accordance with logarithm curves, as was the case with the continuous-slip regulator. Assuming that constant power was required throughout the pass when a bar was between the rolls, and as the power given by the motor was practically constant, the power given by the flywheel would also be practically constant, or in each small interval of time, the same amount of stored energy was to be given out by the flywheel. The speed would, therefore, fall during the pass in accordance with the straight-line law, and would rise again in the interval between passes, also in accordance with the straight-line law, and there would be no logarithm curves for the rise and fall in speed as with the continuous-slip regulator.

The author also discussed the arrangement of motor and flywheel to suit power supply, the Ilgner system of driving three-phase current for merchant mill driving and friction losses.

Economy.

Various economies could be effected by electrical driving when properly applied, but one of the principal economies was that of the cost of power. The electrical drive often enabled cheap power to be used when it could not be transmitted or applied in any other way, and also in many cases it afforded a means of enabling power to be generated cheaply, so that in planning an electrical drive every care should be taken to make use of its natural advantages as far as possible.

In a large city where land was expensive, and where facilities for generating power in each individual works were far from the best, it was generally found to be most economical to buy power from the supply authority where the amount required was not very large, because power could be generated in bulk in a power station and distributed to the various works more cheaply than the works could generate it themselves. Where works were not situated in a city, and where the cost of ground, etc., was much less, it was generally found that the works themselves could generate more economically unless the amount of power required was very small. Where cheap power was available, it must be applied as economically as possible and it would be seen from what had been said in the foregoing, that considerable care must be exercised in applying a motor and flywheel to a rolling mill in order to ensure that the power was utilized as cheaply as possible if it was desired to obtain economy in working.

OPENING ANNOUNCEMENT.

The Canadian Cleveland Drill Co., have established themselves at 24 Adelaide Street, West, Toronto, where in addition to the headquarters office, a warehouse for the purpose of carrying a large and complete line of "Cleveland" pneumatic tools, and a fully equipped machine shop to take care of repair requirements, are also located. Exclusive "Cleveland" selling rights for Canada have been secured, and, therefore, everything, including correspondence, pertaining to Canadian business will be handled at the above address. The new enterprise will materially tend to improved service and prompt delivery, obviating, as it will, the harassing delays inseparable from the customs regulations. At a later date, a full line of "Cleveland" rock drills and air compressors will also be carried in stock. Mr. H. C. White is manager of the new undertaking, and needless to say is brimful of enthusiasm for his work. Numerous inquiries and orders have already been received for pneumatic equipment.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

FOUNDRY AND MACHINE SHOP.

Toronto, Ont.—Fire did $300 damage to the Valleyfield Iron Works here on Peter street.

Toronto, Ont.—McGregor & McIntyre, Pearl street, are contemplating the erection of a foundry on Pearl street to cost $30,000. New machinery will be installed.

Hull, Que.,—Fire did $2,000 damage to the plant of the Walter's Axe Company recently.

London, Ont.—Assembling shop, threshing machines of Geo. White & Sons, Co., Cabell avenue, London, were damaged by fire to the extent of about $25,000. Tools and stock destroyed will be replaced at once.

Gananoque, Ont.—Mr. Ketchem reported receipt of a letter from an English manufacturer regarding the establishment here of a malleable iron works, and asking what advantages the town could offer.

Brandon, Man.—The Brandon Construction Co. plan to convert their shop into a woodworking factory. Work on alterations will start at once, and new machinery will be installed.

St. Boniface, Man.—Fire completely destroyed the plant of the Winnipeg Steel Granary and Culvert Co. recently. The loss is placed at $15,000.

Brantford, Ont.—The Cockshutt Plow Co. has acquired the Adams Wagon and Brantford Carriage Co., and large additions will likely be made by the new owners.

Edmonton, Alta.—The Van Slyke Plow Co. have been incorporated and will locate here. They will manufacture plows, farming implements, etc.

Welland, Ont.—Welland's latest industry is a nut and bolt works, which has secured a site in Industrial Park. A plant will be erected at an estimated cost of $50,000.

Lunenburg, N.S.—The annual meeting of the Lunenburg Foundry Co. was held last month. Steps are being taken to augment the plant.

Ottawa, Ont.—Incorporation has been granted to the Algoma Steel Bridge Co. of Winnipeg, capitalized at $40,000. The promoters are A. Y. Bayne, M. McCollum, A. A. Gould, W. S. Thomas, all of Winnipeg, and M. B. Stone, of Minneapolis.

Fredericton, N. B.—The city council will press its case at Ottawa in the endeavor to secure the location of the St. John and Quebec Railway car shops here.

Port Arthur, Ont.—The Industrial Commissioner is endeavoring to secure the western branch of the Canada Car Company for this city.

Montreal, Que.—The G.T.R. recently placed orders for over four thousand cars of various kinds. These include 44 passenger coaches, 23 baggage cars, 300 box cars, and 1,000 coal cars.

Kingston, Ont.—At a meeting of the North American Smelting Co. held here early last month, the directors voted to rush the installation of the furnaces and power plant at the smelter. The company expect to begin operations by May 1st.

Vancouver, B. C.—The Granby Consolidated Mining and Smelting Co. will erect a smelter at Goose Bay, in the Portland Canal district early this spring. The proposition will entail an expenditure of $1,000,000.

Toronto, Ont.—The Wolsley Tool and Motor Co. are erecting a garage at 81 Avenue Road. This marks the coming of the first automobile manufacturer to Canada, and if business warrants it, the syndicate will invest heavily in a motor factory.

Belleville, Ont.—Marsh & Henthorn, foundry and machinists, contemplate the erection of new foundry and machine shops. President and manager, L. W. Marsh, Belleville. The company are waiting until the C. P. R. is located. New buildings will probably cover two acres.

Port Colborne, Ont.—That the Buffalo Union Furnace Co. will erect a plant here is now assured, since the Dominion government has granted the concessions asked for. The Port is now counting on the establishment of several other industrial concerns.

Kerrobert, Sask.—N. T. Elliott has established a machine shop here. He has erected a suitable building and completed the installation of a lathe and complete blacksmith's outfit. He contemplates adding an iron planer, trip hammer, and screw machine.

Tilbury, Ont.—Temporary quarters have been secured for the Canadian Top Co. New machinery will be purchased. Plans for a new factory will be prepared later. It is rumored that the factory may move to Chatham. Machinery loss in recent fire was $12,000.

Port Arthur, Ont.—Acting for Mackenzie & Mann and an English syndicate, J. M. Fraser, manager of the Atikokan Iron Co., has submitted to the city application for a $5,000,000 plant here. The city will be asked for certain concessions, one of which is for a 400-acre site at Bare Point.

Bridgeburg, Ont.—Plans are being prepared for foundry warehouse, shops, offices, etc., for the Tuttle-Bailey Manufacturing Co., Cleveland, manufacturers of Ferro-Steel Heating Registers. Supt. Peter Gordon, Jarvis street, Bridgeburg. Foundry, warehouse, Japan ovens, office and machine shop equipment will be required.

Kindersley, Sask.—A large machine shop, foundry and garage is being established in Kindersley by Messrs. Hay, Pine & Co., formerly of Kingston, and themselves practical machinists. They are quite optimistic over the opportunity they believe exists in their line. A seventh lumber yard is also being established by J. H. Hahn, a local man, who believes the prospects for the coming year warrant the undertaking.

Hamilton, Ont.—A site has been secured for a machine plant, cost $200,000, on Sherman avenue, for Brown, Boggs & Co., machinists, Victoria ave. and King William street. President, J. M. Brown. Manager, W. E. Blanford. The company, in proposed new plant, will specialize in manufacture of tools and machinery, and the purchase of a large amount of machinery is involved in contemplated expansion.

MUNICIPAL.

Dunnville, Ont.—The ratepayers carried the by-law to raise $24,000 for waterworks improvements.

Vernon, B. C.—A by-law to borrow $12,000 for sewerage extension purposes was passed by the council.

Owen Sound, Ont.—The ratepayers passed the hydro-electric and gas extension by-laws.

Berlin, Ont.—The ratepayers carried the following by-laws:—Waterworks extension, $100,000; drainage improvements, $10,735; extending street railway, $7,400; and trunk sewer, $1,700.

Ingersoll, Ont.—The ratepayers passed the $125,000 waterworks by-law.

Barrie, Ont.—The ratepayers passed the by-law to raise $35,000 for sewers.

Carleton Place, Ont.—The ratepayers passed the by-law to spend $100,000 on a waterworks system.

Hamilton, Ont.—The following by-laws were passed by the voters:—Waterworks extension, $650,000; Gore Park public convenience, $14,000.

Selkirk, Man.—Two by-laws were passed by the ratepayers recently:—One confirming the agreement between the town and the W. S. and L. W. Railway regarding electric power; and the other to raise $25,000 to establish a municipal lighting system.

Renfrew, Ont.—The by-law to spend $60,000 for additional improvements to the power plant carried.

Cornwall, Ont.—The ratepayers expressed themselves as favorable to municipal owner-

ship of electric light and gas, but were opposed to buying the present plants.

Woodstock, Ont.—The ratepayers passed the electric light by-law recently.

Killarney, Man.—The by-law to raise $14,000 to purchase the electric light plant was defeated.

Vancouver, B. C.—The B. C. Electric Railway Co. will spend over a $1,000,000 during the coming year. This will double the output of the electric power plant.

Toronto, Ont.—The ratepayers carried the by-law to raise $2,200,000 for hydro-electric extension.

Brampton, Ont.—The by-law to purchase the Brampton Electric Light Franchise was carried by the ratepayers.

BUILDING NOTES.

Ottawa, Ont.—The Public School Board contemplate an expenditure of $80,000 for an addition to Kent street technical school.

St. John, N. B.—F. R. Dearborn contemplates the erection of a six-storey building on Water street. He also contemplates converting his building on Prince William street into an up-to-date office building. A passenger elevator will be installed; also a series of fire-proof vaults.

Toronto, Ont.—A. B. Coleman is about to erect a $1,000,000 apartment house on the north side of the Rosedale ravine.

Vancouver, B. C.—Messrs. Parr and Fee, architects, have prepared plans for a six-storey building here for John Lewerke.

Guelph, Ont.—The Masons of this city will erect a three-storey building. A passenger elevator will be installed.

Calgary, Alta.—The Alberta Commercial Travellers' Association will erect a $100,000 building here. It will contain club rooms, stores, and offices.

Edmonton, Alta.—J. H. Picard has secured plans for an eight-storey business block here. Construction will not be undertaken until the spring of 1913.

Edmonton, Alta. Armstrong Bros. are preparing to erect an $85,000 building here in the near future. It will be of brick and steel construction.

Toronto, Ont.—P. J. Mulqueen has obtained a permit for a five-storey hotel here on the east side of Yonge street, to cost $80,000.

Brantford, Ont.—The Dominion government will erect a $2,000,000 post office building here. They have secured a $40,000 site.

PLANING AND SAW MILLS.

Montreal, Que.—The sash and door factory of Joseph St. Louis on Simard avenue, was destroyed by fire recently.

Milverton, Ont.—The C. B. Honderich Co. which conducts a planing mill here contemplates going into the manufacture of furniture and will probably erect a new plant here.

St. Mary's, Ont.—The planing mill owned by George Brown & Company, was gutted by fire recently. The machinery and contents were entirely destroyed and the walls of the building damaged. The damage is estimated at between $8,000 and $10,000, partly covered by insurance.

Calgary, Alta.—The Dominion Saw Mills and Lumber Co., the large English corporation which within the last year or so has acquired extensive lumber milling interests in British Columbia, has decided to locate its chief office for the manufacturing end of the business in the city of Calgary.

Lethbridge, Alta.—A. G. McLaren has made a proposal to the city to erect a huge sawmill plant at a cost of two and a half million dollars in return for certain concessions. The industrial committee has the proposal under consideration.

St. Mary's, Ont. — The St. Mary's Wood Specialty Co. suffered to the extent of about $20,000 by fire, from a cause unknown. There is insurance of $17,000.

GENERAL MANUFACTURING.

Calgary, Alta.—The Canada Malting Co. will erect an extensive plant here to cost $250,000. It is expected that a by-law will be submitted to give the company a fixed taxation for a period of years.

New Westminster, B. C. — The Portland Cement Construction Co. are planning to erect a plant at Tod's Inlet. It will be equipped in the most modern fashion, and will cost approximately $1,000,000.

Port Arthur, Ont.—The Twin City Bedding Co. are taking steps to enlarge their present factory.

London, Ont.—A number of local men are behind a company which will start a new box factory here. They will manufacture cigar boxes exclusively.

Winnipeg, Man.—It has been announced that the Quaker Oats Co. of Peterboro' will erect a large cereal plant and flour mill here in the spring.

Vancouver, B. C.—The factory and woodworking plant of the Terminal Construction and Manufacturing Co., West Fairview, was destroyed by fire recently. The loss, $25,000, is partially covered by insurance.

REPUTATION COUNTS

in Machine-Tool Manufacture as much as anywhere.

The reputation of ***Drummond*** Machine Tools is well established in England, Australia, New Zealand, South Africa and the Argentine.

In introducing these tools into Canada, this reputation will not only be ***upheld*** but furthered.

These are inexpensive tools, designed for repair work in motor garages, commercial auto vehicle yards, railroad shops, etc.

GALT FOUNDRY CO. GALT, ONT.

Montreal, Que.—Fire did $25,000 damage to the Dominion Button Co. here some time ago.

Sarnia, Ont.—The Ontario canners are planning to instal additional machinery and otherwise augment their plant in the near future.

Kincardine, Ont.—Mr. Coombe has bought out the Coombe & Watson Chair Factory here. He may possibly start another factory here to manufacture a different line of goods.

Bracebridge, Ont.—The Bird Woollen Mills Co. will erect a three-storey re-inforced concrete building here, 30 x 100 feet. They were voted certain concessions by the ratepayers.

Fort Erie, Ont.—Chas. Landon has established an electrical novelty factory here. He has installed a quantity of modern machinery.

Owen Sound, Ont.—J. H. Cole has about completed arrangements to establish a bolt and nut factory here. The ratepayers have voted to grant him assistance.

Rosthern, Sask.—The Union Supply Co. will erect a big flour mill here to replace the one recently destroyed by fire.

Blairmore, Alta.—A number of eastern capitalists have purchased a site here and will erect a $75,000 plant to manufacture fire brick.

Winnipeg, Man.—The Canadian Enamel Concrete Brick and Tile Co. will establish a plant here to manufacture a new kind of concrete brick. $150,000 worth of machinery will be bought.

Medicine Hat, Alta.—The Steam Laundry Co. are preparing to erect a two-storey brick building here. They will spend $25,000.

ELECTRICAL.

Ottawa, Ont.—Ottawa Electric Railway Co. contemplate purchase of oil engines or large steam engine to produce between three and four thousand horse power as an auxiliary plant.

GENERAL MANUFACTURING.

Bassano, Alta.—A site has been purchased for cold storage plant for Calgary Brewing and Malting Co., Calgary. Erection of plant will commence early in the spring.

Bancroft, Ont.—S. Plows' grist mill, E. Reid and Sons' woollen mill, J. D. Payne's machine shop, and the electric light plant were destroyed by fire on January 25.

Sault Ste. Marie, Ont.—Negotiations are in progress for extension to paper mills of Lake Superior Paper Co. It is thought that the concessions the town is willing to grant to company will be considered satisfactory by directors in England whom Mr. Talbot will interview this month. Plans entail expenditure of $1,000,000.

Fonthill, Ont.—Plans are being prepared for canning factory for Dominion Canners, Ltd., Hamilton. Plans to be ready in about three weeks, when contracts will be called.

Frank, Alta.—Keystone Portland Cement Co. are contemplating the erection of a new cement plant. Vice-president, E. A. Cunningham, Lethbridge; director, P. Lund, Wardner, B. C. Building will probably commence at once.

Strathroy, Ont. — Strathroy Canning Co. (Dominion Canners, Ltd.) Hamilton, plan to erect a two-storey extension to canning factory. It is stated that plans are being prepared and that additional equipment will be purchased. Cost $10,000.

TRADE GOSSIP.

The Corbet Foundry and Machine Co., Ltd., Owen Sound, Ont., report having had a first rate year in 1911. Prospects for 1912 are very bright, there being a large amount of work in hand and in view. Last summer the firm built five steel bridges, as well as a large amount of marine and structural steel work.

The Wm. Kennedy and Sons, Ltd., Owen Sound, Ont., have on hand a contract for seven cement pulverizers for The Canada Cement Co., Montreal, together with a great deal of other work. Their machine shop is now working night and day. The steel foundry is also fully employed. In the coming spring it is intended to largely increase the facilities for handling work now existing in the steel foundry, with a view to increased output.

Heenan & Froude, Manchester, England, have been awarded a silver medal by the Royal Sanitary Institute for their "Trough Grate for Refuse Destructors." Before deciding the award, two experienced judges went to Hertford to see the grate and clinkering apparatus in operation. Laurie & Lamb, Board of Trade Building, Montreal, are the Canadian representatives.

H. W. Ward & Co., Machine Tool Builders, Birmingham, England, inform us that they have made arrangements with the purchaser of the freehold of the Lorraine-Dietrich Works, Bournbrook, for their occupation, to relieve the congested state of their present works, and afford greater facilities for the manufacture of their products. They are installing new machinery, and inteud commencing operations immediately at the beginning of the New Year.

Mussens, Limited, dealers in railway, contractors, mining and municipal machinery and supplies, have sent us an office calendar for 1912. A number of the principal lines handled by the company are displayed on the various sheets of the calendar.

TENDERS AND CONTRACTS.

Victoria, B.C.—The city council on the recommendation of the water commissioner decided to purchase 10,000 feet of ten-inch pipe, 10,000 feet of eight-inch pipe, 50,000 feet of six-inch pipe, and 50,000 feet of four-inch pipe at a cost of $55,000. In addition, there will be purchased 1,220 water meters of the Trident type at a cost of $17,670.

Winnipeg, Man.—Tenders for the supply and installation of a five million gallon horizontal turbine pump driven by an induction motor, direct-connected, will be received until March 1st, 1912.

Hamilton, Ont.—The Hamilton Bridge Company has secured the contract for the erection of the new buildings for the Steel Company of Canada. Total cost, $140,000.

Lethbridge, Alta.—The contract for street car equipment has been awarded to United States Steel Products Co., 706 McArthur Bldg., Winnipeg.

THE DOMINION STEEL CORPORATION.

At a meeting held Jan. 16, the stockholders of the Dominion Steel Corporation voted in favor of issuing $7,000,000 of the $17,000,000 authorized 6 per cent. preferred stock, to be exchanged for the 6 per cent. income bonds of subsidiary companies. The program of improvements and extensions now under way or planned for the immediate future includes 10 new collieries, to be operated by the Dominion Coal Co., and two blast furnaces, new coke ovens and additional machinery, to be installed at the steel plant.

CATALOGUES RECEIVED.

The National Machinery Co., Tiffin, Ohio, have again issued a catalogue of their well-known bolt and rivet headers and forging and upsetting machines. These are now too well known to call for extended comment. The catalogue is expensively gotten up and is a fine example of the printer's art. Those desiring a copy should ask for catalogue E.

The Independent Pneumatic Tool Co., Chicago, Ill., have sent us a copy of their circular O, descriptive of the various **Thor** pneumatic tools which they manufacture. These include riveting and chipping hammers, piston air drills, grinding machines, close quarter piston air drills, pneumatic stay-bolt drivers, etc. The company will be glad to demonstrate the merits of their tools to any responsible concern by a thirty days' trial.

The National Tube Co., Pittsburgh, Pa., have favored us with a copy of their Bulletin No. 7, dealing with the Regrinding Valves made by them. The regrinding of one of these valves does not necessitate its removal from the pipe line, nor the use of a regrinding machine. This feature is attained by a novel method of uniting the body of the valve with the bonnet, which it would be difficult to make clear without an illustration. The bulletin, however, explains this and other features, and will be mailed to parties who are interested.

The Reliance Electric and Engineering Co., Cleveland, Ohio, have issued Bulletin No. 7010, setting forth the merits of their Automatic Starting Control for motor-driven machinery, introduced to prevent injury to motors at starting, due to the hastiness or inexperience of the operator. The bulletin is illustrated by numerous photographs of motor-driven machine tools fitted with this device.

The General Fire Extinguisher Co., New York, have mailed us their January Bulletin, dealing with the Grinnell Automatic Sprinkler Literature on the subject of fire protection is always of interest to manufacturers, superintendents and all business men.

The L. S. Starrett Co., Athol, Mass., have issued a handy little folder dealing with their Vernier calipers, which may be had in various sizes and graduated in either or both English and Metric divisions. A section of the booklet is devoted to instructions on "How to Read the Vernier."

D. Van Nostrand Co., 23 Murray Street, New York, have mailed us the latest monthly list of scientific books published by them.

Verity's Ltd. Aston, Birmingham, England, have sent us illustrated price lists of their English-made Tungsten lamps, and also of their Aston Farm House lighting sets. These consist of a gasoline engine and a dynamo direct-coupled and mounted on one base. An accumulator and switchboard complete an outfit, which is to be recommended on account of its easy portability. These sets are supplied in six sizes, suitable for from 28 to 225 lamps of 20 watts. Prices are quoted in Canadian currency, and are very reasonable.

The Lunkenheimer Co., Cincinnati, Ohio, has recently issued an attractive booklet describing their various types of blow-off valves, and they will be pleased to send it upon request.

The Westinghouse Electric & Manufacturing Co., East Pittsburg, Pa., have sent us their circulars No. 1028 and 1190. The first illustrates and describes numerous examples of rotary converters, while the second deals with type E engine-driven A. C. generators.

AMERICAN MACHINISTS LIMITED
367 ST. JAMES STREET, MONTREAL

The Allis-Chalmers Co., Milwaukee, Wis., have forwarded a copy of their Bulletin No. 1083, setting forth the distinctive features of their D. C. generators and showing numerous examples of their application to the direct driving of machine tools.

The Canadian Gasket Co., Bridgeburg, Ont., send us their price list of gaskets. Among other types listed are plain and corrugated copper gaskets, those with asbestos cord-filled corrugated, smooth copper gaskets with asbestos filling, lead gaskets for ammonia fittings, oval gaskets for man-holes, hand-holes, etc.

Poetter, G. M. B. H., Ltd., Dusseldorf, Germany, have sent us a copy of their latest catalogue of gas producers, constructed on the Hilger system. These producers have a slowly rotating ash pan and a star shaped grate. Through the rotation of both of these the ash in the producer is kept constantly in motion, thus preventing formation of clinker. Moreover, by these means new surfaces of the fuel are being constantly brought under the influence of the blast, with the result that gasification is greatly hastened. A gas producer of 10 feet internal diameter is claimed to be capable of dealing with 25 long tons of coal or 36 tons of lignite per 24 hours.

Chambers & Simpson, Engineers, Toronto and Brantford, have gifted us the handsome leather-bound pocket diary issued by their principals, the Campbell Gas Engine Co., Halifax, England. Besides containing a large amount of highly instructive and valuable data dealing with the various products of that firm, there is a most interesting detailed calendar of prominent occurrences and feast days, and in addition to a neatly arranged memorandum department, an accident insurance coupon contributes to its further possible utility.

Darling Bros., Ltd., Montreal, have issued the 1912 edition of their handy little condensed catalogue of steam specialties, feed water heaters, vacuum valves, feed pumps, etc. A double frontispiece shows portraits of the firm's engineers and representatives in Montreal, Toronto, St. John, N.B., Winnipeg and Vancouver. The little book measures 6 x 3½ inches, and is well printed on faced paper.

BOOK REVIEWS.

"Street Lighting", by J. M. Bryant and H. G. Hake, has just been issued as Bulletin No. 51 of the Engineering Experiment Station of the University of Illinois. Efficient and economical street lighting is a subject on which little information of a definite and tangible character has been published. Bulletin No. 51 is designed to supply such information concerning electric street lighting. The subject has been treated in a simple, direct manner, and while of especial interest and value to the technically trained illuminating engineer, will appeal particularly to city councils and central station managers. The general theory and construction of electric lamps, both incandescent and arc, are discussed, together with the standard systems of electric distribution for lighting, and accepted methods for the measurement and study of illumination, with and without shades and reflectors. These principles are then applied to the study of street illumination, curves and calculations being given to show the candle-power distribution for the various lamps used, equipped with their proper glassware and reflectors, and others to show the illumination along the street for representative installations and conditions. Based upon these results, a discussion is given of the proper lighting of business streets, cross streets, boulevards, residence streets and outlying districts. The subject of economy for the several systems and lamps is thoroughly discussed—the initial cost, up-keep, interest and depreciation of various lamps and equipment are considered in tables and curves showing their relative economy at standard costs of power

STEEL PLANT FOR VANCOUVER.

The coast district of British Columbia is known to be rich in iron deposits of excellent quality, so that it is not surprising to learn that it is proposed to form a company in Vancouver with the object of establishing and operating a steel plant in, or near, the city. Prominent in the undertaking are George M. Gibbs, Vancouver; Henry K. Owens, Seattle, and James D. Sword, Vancouver. It is understood that property containing very large deposits of iron ore has been secured on Louise Island, one of the Queen Charlotte group. It includes nine claims adjoining one another and covering an area of approximately four hundred acres. The ore is said to be extremely rich in metallic iron, and as the present daily consumption of pig iron alone on the Pacific coast is said to be upwards of 750 tons it will be seen that future prospects for a plant of this description are very bright.

ELECTRICAL MACHINERY, ITS CARE AND HANDLING.

By Roderick Grant, Toronto.

WE are aware how difficult it is to get engineers or attendants, who have had little or no electrical experience, to appreciate how easily a serious fault may develop from what might appear to be a trifling cause, so we would urge the necessity of giving to the brushes, etc., the most careful attention and of taking prompt action to remedy any condition that might conceivably cause trouble. It augurs well if a highly polished dark skin forms on the commutator surface, indicating, as it does, that there is the minimum of wear. The surface then, on no account should be disturbed with sandpaper, for an occasional wipe with a clean dry rag will usually prove to be all the treatment required. It is sometimes advantageous, however, to wipe the commutator with an oiled rag, especially if the brushes become noisy. This treatment also removes any gummy substance present, and which on no account should be allowed to accumulate.

Defective Insulation Due to Oil Leakage.

At this time of day, when the disastrous results to insulation from moisture or dampness are so well known, it is perhaps needless to insist on the precautions to be observed in that direction, but there is another source from which impaired insulation results equally disastrous, and we regret to say of much too common occurrence. We refer to the indiscriminate use of lubricating oil. It is of course necessary that all bearings should be thoroughly lubricated, but great care should be taken to see that the oil does not overflow, run along the shaft or collect about the frame where it might affect the windings. In most modern machines, the armature is protected by shields on the shaft which arrest the creeping oil before getting to the windings, and manufacturers have given considerable attention to the design of lubricators, to insure that no splashing takes place. The trouble to which we refer, is in most cases, simply due to flooding, and not only is it wasteful but at the same time positively dangerous.

Bearing Lubrication and Effects of Wear.

Electric motors and generators are as a rule provided with ring lubricators which under favorable conditions give perfect service. An occasional examination should be made, however, to ensure that they are working freely, as a slight deposit of sediment in the oil reservoir will often prevent the ring from being carried round on the shaft. Further, it is not unusual for a ring to spring from its seat by increased vibration, and to

50 Pearl Street, Toronto, Canada

take up an ineffective position. This trouble can be guarded against by soldering a piece of stout wire across the slot in the bearing wherein the ring lies. Only good clean mineral oil should be used, perfectly free from grit, and the reservoirs should, periodically be thoroughly cleaned out.

Perhaps the chief importance of keeping the bearings in good order lies in the fact that if any wear takes place the armature is thrown out of centre, and the pull exerted by the pole piece toward which it lies becomes tremendous as the neutralizing influence of the opposite pole is lessened. This not only disturbs the magnetic and electrical balance, causing undue heating of the armature and sparking at the brushes, but the wear of the bearings is greatly accelerated until finally the armature rubs on the pole face, damaging more or less severely the insulation. The necessity therefore of keeping the armature exactly central or equidistant from the field magnets will be readily appreciated and frequent inspection should be made in order to ascertain if any wear is taking place. To this purpose, it is advisable where several machines are in use, for the engineer to have at hand a number of flexible strips of wood of the required lengths and thickness. These may be conveniently kept together by means of a ring passing through a hole near one end. Each strip can be inserted in turn and the exact amount of clearance at all points thus readily determined. Although this method is the more reliable the same object may be accomplished by holding a lamp at one end of the armature, when the amount of clearance may be seen from the opposite end. It is possible, however, that the armature may be out of centre without any appreciable wear having taken place at the bearing. A bent shaft, the shifting of one of the field magnets, or a loose armature winding would each contribute to this. In any case, it is no difficult matter to determine exactly what is at fault.

The bearing at the driving or pulley end of the shaft, owing to the extra strain, is subject to most wear. This if once started, for reasons already stated, develops rapidly, so that, on the least indication of this trouble, preparations should be promptly made to have the fault remedied at a time that will cause least inconvenience. The danger of having a bent shaft is not so great, as not only are special precautions taken by all reliable makers to obviate such an occurrence, but it is only under certain conditions that such a thing would be likely to happen. For instance, if the armature were unusually long, the danger would be increased; or if by any chance the machine were allowed to race and exceed its normal rate of speed, the centrifugal force would exert a tendency more or less severe in that direction.

In spite of the precautions that are taken in dynamo and motor design, vibration will sometimes cause a slight displacement of the pole pieces and of the field magnet coils. The measures to be adopted under such circumstances will entirely depend on the manner in which these parts have been fixed, but on the location of the fault, there is seldom much trouble experienced in making the necessary adjustment. Projecting coils on the armature should be pressed carefully and firmly into position and if necessary held by extra binding wire.

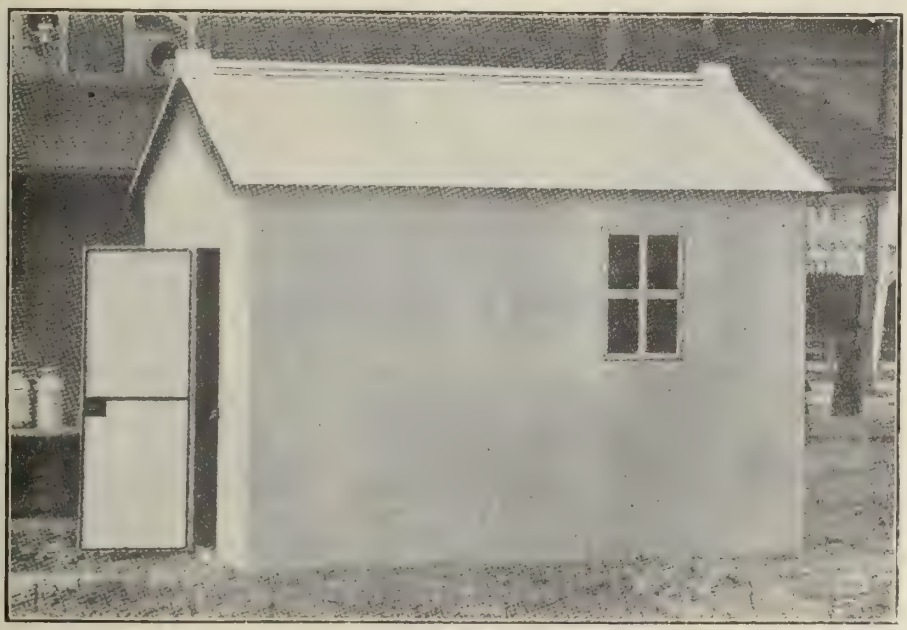
RUBY PORTABLE STEEL BUILDINGS



The above cut illustrates one of the small steel buildings, 9ft. 4in by 11ft. 8in with 8-ft walls used for storing oil, tools, etc. This is the type of small house adopted as standard by the M.U.R. and D.U.R. Traction companies. $140.00, f.o.b. Toronto

are economical in the truest sense of the word. Not only do they effect a great saving in insurance, cost of upkeep, and in the time saved, by the ease with which they can be taken apart and put together again; but being water and weather-proof, they absolutely protect their contents from any damage. Contractors will appreciate this. The steel frame and heavy galvanized steel inclosures are sectional. Every similar part is interchangeable. The wall and roof sections fit together on the tongue and groove principle in perfect weather-tight joints, making, altogether, a house complete in every way and perfectly adapted to the purpose for which it is meant.

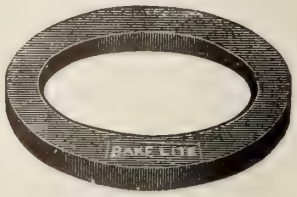
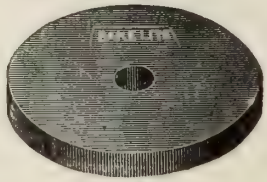
These are the telling points about



Bakelite

Valve Discs

THEY will not leak under high temperature, excessive pressure or when used in acids or other special liquids. Neither cold water, dry or superheated steam has the least effect upon them. BAKELITE Discs are a gas-tight fit



BAKELITE is a successful substitute for expensive metal. Its structure is fibrous, giving strength and hardness. It can be reground and refaced, always retaining a uniform surface. It cannot be injured except by accident or friction.

Remember Bakelite PUMP VALVES do not warp with changes of temperature.

Order your valves fitted with Bakelite Valve Discs and stop that perpetual annoyance and expense caused by leaking valves. Depend upon it, Bakelite Valve Discs will not leak.

Write for prices or ask your dealer.

39-1

MORE AIR
FOR THE MONEY

The class "NE-1" compressor delivers more air for the money invested and the power consumed, month after month, than any small compressor heretofore offered. It should, however, it's manufactured to be a leader. It embodies all the modern ideas in air compression.

The "NE-1" is obviously an aristocrat. When you consider its construction: the large, amply oiled bearings, the perfectly balanced rotating and reciprocating parts; the large, free air ports; the high grade workmanship and many other features which it embodies, and which are detailed in our Pamphlet K-92, you will agree with us that it is a superior little machine.

What we mean by advertising our Boilers as "Built Right"

With boilers designed and built to standard specifications and made to pass the same inspection, it would seem that a boiler built in one shop should be as good as that built in another. It should be—often it is—but just as often it is not.

By combining the facilities and tool equipment offered in a shop as large as ours, with the constructional kinks and little "know hows" learned in our fifty years of boiler making, we turn out our boilers with a snap and finish that stamps them as BUILT RIGHT — Waterous Made—before you read the name plate.

Goodhue Belts

Mean Minimized Belting Expense,
Mean Highly Efficient Belting Service.

If there is any manufacturer who is not acquainted with this Belting, he should make it a point to get acquainted with it at once. It is a Belting that is saving every user money.

Saving money because it stretches from 15% to 25% less than any other Belting on the market, thereby eliminating much lost time that would be incurred in tightening.

The "GOODHUE" belt is highly efficient in service, as it has a positive cling that means a certain transmission of every particle of power developed.

According to the conditions where the belt has to run, we recommend our "EXTRA," "STANDARD," or "ACME WATERPROOF" Belts.

An inquiry will prove valuable to you.

J. L. Goodhue & Company, Ltd., Danville, Quebec

The advertiser would like to know where you saw his advertisement—tell him.

THERE'S A COPY FOR YOU

If you are interested in selling a line of power transmission appliances that has strong talking points, that has distinctive merit, that has unique individuality, that appeals to manufacturers because it embodies the perfection of modern principles of power distribution and control; or if you are a manufacturer and contemplate using any new power transmission equipment, you want this catalogue, "The POSITIVE Line."

You can't afford not to investigate POSITIVE Combined Jaw and Friction Clutches, Combination Split Pulleys, Shaft Hangers, Pillow Blocks, Compression Shaft Couplings, etc., if you want to handle or use the line that is so entirely different, better and far in advance of existing designs of such appliances, that it has revolutionized the transmission of power in manufacturing plants and has established a higher standard of dependability, durability, economy and efficiency in industrial operations.

The catalogue also contains some handy engineering tables and formulae. When you ask for it, don't fail to state, "Second edition of The POSITIVE Line."

Why Didn't We Protect Those Windows, too, With Fenestra Sash ?

What *water-tightness* is to an ocean liner—
What *burglar-proofness* is to a bank—
What *strength* is to a sky-scraper—
Fireproofness is to a modern industrial building.

It would seem hardly less logical to handicap the watertight compartments of a ship with frail partitions, to offset the 3-foot cement floors of a vault with a wooden trap-door, or to construct a Singer building on a doubtful footing, than it is to build a modern factory of fire-proof construction, equip it with sprinkler-systems, fire-doors and fire-alarms, and then to demoralize the whole chain of expensive and otherwise carefully planned fire-protection by tolerating the weak link of wooden sash.

Scientific factory construction relegates wooden sash to the day of clapboard walls, plank floors and shingle roofs.

Where else can you reasonably class them ?

FENESTRA FIRE PROOF SASH

glazed with ordinary wired glass is positively the last word in fire-resistance as applied to windows.

Common sense dictates that.

Actual fires have proven it beyond question. In a fire at Stoneham, Mass., in September, a building equipped with FENESTRA SASH was practically surrounded by a burning varnish factory. Reglazed after the fire, the Sash were as good as new. Photographs on request.

Remember, too, that FENESTRA SASH also *light* and *ventilate* a building better than any others. They're made to suit individual needs.

If you are interested in the planning or construction of a building where *light*, *fresh air*, and *fire protection* are essentials, let us send you our "Fenestra" Catalog.

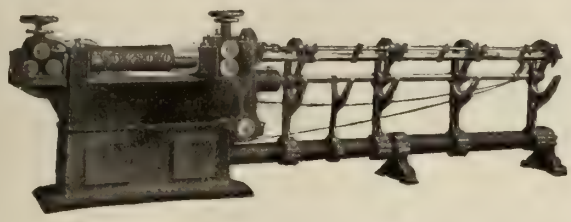
QUALITY AUTOMATIC WIRE STRAIGHTENERS AND CUTTERS



We could build cheaper machines if we overlooked certain details, but QUALITY MACHINES have always been our aim.

The design is correct, construction accurate, adjustments quick and convenient, it operates with a minimum amount of power and runs all day.

Handles any kind of wire directly from the coil, makes it perfectly straight, and cuts accurate lengths.

If your stock is squares, hexagons or flats we can furnish equally efficient machines for straightening and cutting from the coil.

The F. B. SHUSTER CO.
(formerly John Adt & Son)

Box 155, NEW HAVEN, CONN. Established 1866

ELASTIC ROTARY BLOW RIVETING MACHINES. Special Automatic Machinery for Buckle Tongues, Cotter Pins, Staples, etc.

PERFORATED METALS

Describe your need.

MACHINERY WANTED AND FOR SALE

AGENTS WANTED.

AGENTS WANTED—English firm manufacturing lifting tackle of every description and with merchant department for handling all classes of engineering material want Agents in Canada. Box 75, MACHINERY AND MANUFACTURING NEWS, 88 Fleet Street, London, England.

SITUATION VACANT.

WANTED—A good nickel-plater for a stove concern. Good wages; steady job. Apply "Plater." CANADIAN MACHINERY, Toronto.

WANTED—Foreman die and tool maker, experienced in making pipe and bolt threading dies, also who can work from blue prints. Steady position for right man. Apply BORDEN-CANADIAN CO., 66 Richmond St. East, Toronto.

BELTING, PACKING, ETC.

BELTING FOR SALE—800,000 feet of best quality leather, rubber, hair and canvas belting, bought from bankrupt manufacturers at 25% to 75% less than the regular value. Also a large quantity of slightly used belting, piping, chains, rails, pulleys, hangers, cotton waste, etc., at very low prices. Send for catalogue. IMPERIAL BELTING AND SUPPLY CO., 5 Queen Street, Montreal.

BELTING, RUBBER, CANVAS AND LEATHER, Hose Packing, Blacksmith's and Mill Supplies at lowest price. N. Smith, 138 York Street, Toronto. (2tf)

MACHINERY FOR SALE.

MACHINERY FOR SALE—New and Second-hand Machinery, Engines, Boilers. Wood and Iron Working Machinery and Supplies. Write, stating what you require. Prompt and careful attention to all inquiries. THE ADVANCE MACHINE WORKS CO., Montreal, Que.

FOR SALE—Two Goldie-McCulloch Boilers in good repair—length 14 feet, diameter 5 feet. 74 3-inch flues, 70 h.p. GARLOCK PACKING CO., Hamilton, Ont.

MANUFACTURING CENTRES.

FREE FACTORY SITES—Seven railroads, deep water, Niagara power, natural gas, low taxation, abundant labor. Welland, Ontario. B. J. McCormick. (12y)

WANTED.

WANTED—Every Power House in Canada to remember that C. E. Shedrick, Craig Street West, Montreal, is still repairing measuring instruments, both switch board and portable. Twenty-five years' experience in repairing all kinds and makes on the market. Intregating meters repaired, tested and sealed, and returned on quick time. (12y)

PATENTS FOR SALE.

IRON PURIFICATION PROCESS.—Owners of U.S.A. and Canadian Patents of The Johnson Iron Process for producing superior iron castings at low cost, which is a proved success in England, are desirous of disposing of the above Patents or either of them or of granting licences to use the same in U.S.A. and Canada. Full particulars will be supplied to any bona fide applicant by the owners. VERDON CUTTS & HOULT, 87 Fargate, Sheffield, England. (9)

RUBBER STAMPS, ETC.

B. CAIRNS, MANUFACTURER OF RUBBER stamps, stencils, steel stamps, burning brands 77-79 Queen Street East, Toronto, Ont. (tf)

MISCELLANEOUS.

A BOOK-KEEPING STAFF IN ITSELF—doing the work with machine-precision and accuracy, the National Cash Register. Write us for demonstration literature. National Cash Register Co., 285 Yonge St., Toronto.

COPELAND-CHATTERSON SYSTEMS—Short, simple. Adapted to all classes of business. Copeland-Chatterson Co., Limited, Toronto and Ottawa. (tf)

COUNTER CHECK BOOKS—Write us to-day for samples. We are manufacturers of the famous SURETY NON-SMUT duplicating and triplicating Counter Check Books, and Single Carbon Pads in all varieties. Dominion Register Co., Ltd., Toronto.

DOUBLE YOUR FLOOR SPACE. An Otis-Fensom hand-power elevator will double your floor space, enable you to use that upper floor either as stock room or as extra selling space, at the same time increasing space on your ground floor. Costs only $70. Write for catalogue "B." The Otis-Fensom Elevator Co., Traders Bank Building, Toronto. (tf)

ELLIOTT-FISHER STANDARD WRITING-ADDING MACHINES make toil easier. Elliot-Fisher, Limited, Room 314, Stair Building, Toronto.

FIRE INSURANCE. Insure in the HARTFORD. Agencies everywhere in Canada. (tf)

MODERN FIREPROOF CONSTRUCTION—Our system of reinforced concrete work, as successfully used in many of Canada's largest buildings, gives better results at lower cost. "A strong statement," you will say. Write us and let us prove our claims. That's fair. Leach Concrete Co., Ltd., 100 King St West, Toronto. (tf)

MR. BUSINESS MAN, are you progressive? It's up to you to test "Consolidated," our new process carbon paper. Because it costs less. Soft finish, without smutting, and clear, permanent copies. Write for sample sheets and prices. "Consolidated," Stratford, Ont.

FROM NOW TILL THE END OF THE YEAR we offer unusually good bargains in second-hand Typewriters. They are carefully rebuilt, work and look like new, but the price is a mere fraction of the original cost. Write for catalogue. THE MONARCH TYPEWRITER CO., Limited, 46 Adelaide St. West, Toronto, Ont.

"SYSTEMS" stand for all that is best in loose-leaf binders and supplies, letter-heads, statements and in fact your office stationery of every description. Send us samples of what you are using—we will send you prices that will interest you. Business Systems, Limited, Manufacturing Stationers, Toronto. (tf)

THE "Kalamazoo" Loose Leaf Binder is the only binder that will hold just as many sheets as you actually require and no more. The back is flexible, writing surface flat, alignment perfect. No exposed metal parts or complicated mechanism. Write for booklet. Warwick Bros. & Rutter, Ltd., King and Spadina, Toronto

WAREHOUSE and Factory Heating Systems. Taylor-Forbes Company, Limited. Supplied by the trade throughout Canada. (tf)

FREE INSTRUCTION BOOK

SEND FOR IT TO-DAY

This book should be within instant reach of every engineer. It tells clearly, by photograph and formula, how to use the well-known Smooth-On Iron Cements in repairing boilers, engines, castings, tanks, joints, etc.

Used according to instructions, Smooth-On Cements will save more actual time and money in the engine and boiler room than any single product manufactured. Their uses are innumerable, and their repairs absolutely permanent.

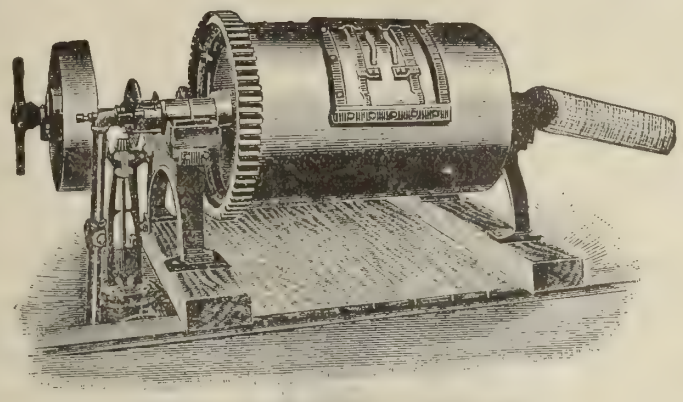
A GOLD MINE

SAVE YOUR IRON



SLY'S PATENT IRON CINDER MILL

Patented, No. 514097. Patented, No. 841728.

may be at your disposal on your very premises. Look out of your side window or back door and see if you have not an accumulation of cupola dump, and other foundry refuse, which is a total loss to you in its present state. Why not add to your profits and install one of the Sly Patent Cinder Mills to reclaim this iron and be astonished at your former loss and pocket the rich returns from your newly-discovered mine.

Sly's Patent Iron Cinder Mill will save 95% of the iron contained in your cupola dump and gangway scrapings and 75% of the coke. Iron is valuable, then why throw it in the dump? Iron recovered by this Mill is better than machinery scrap. Study economy in a foundry and your profits will increase accordingly. Mill will pay for itself three or four times every year, and we have records of Mill paying for itself twelve times a year. Let us know amount of your daily melt and we will quote. *Write for Cinder Mill Catalogue F.*

We also manufacture Cleaning Mills, Dust Arresters, Sand Blast and Foundry Equipment.

THE **W. W. SLY MFG. CO., CLEVELAND, O.**

The Making of Hollow Castings

The recent introduction of King Kore Kompound has now rendered this, once somewhat difficult, part of Foundry practice comparatively easy.

It has, also, reduced the core expense by more than one-half.

This compound is a black, dry powder, and is used as flour is used, but with one-half the quantity is produced greater and better results.

Its use avoids the danger of swelling or "blowing." The core easily comes out of the casting, and when old cores are ground up, in the rattler, or otherwise, the sand so made is used over again.

The core compound it contains, again becomes a binder under heat of the core oven, as it melts, and so it is used over and over again.

This is Foundry Economy; Flour, Rosin, etc., are now luxuries.

A barrel of King Kore Kompound will be sent "subject to approval" to any inquiring mind.

That is the Stevens' System of trying before buying.

I have copies of proportions of compound to sand used and methods followed in core rooms of Foundries in thirteen different States. This information, with other printed matter relative to the subject, will be mailed on request.

I maintain a direct branch at 137 Jarvis St., **Mr. J. M. Mayers, Manager**, Toronto, Ont., where is stocked a supply of **Foundry Facings, Foundry Supplies, Buffing Compositions**, of my own manufacture.

The stamp of quality pervades them all.

FREDERIC B. STEVENS

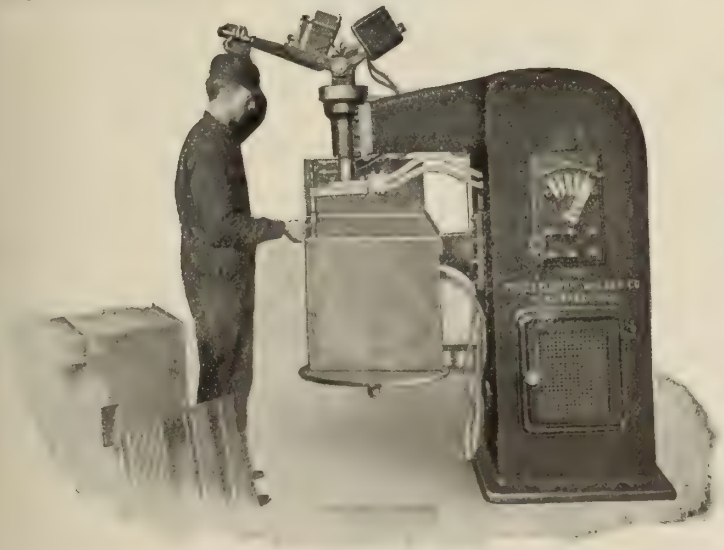
SPOT WELDING

IT TAKES THE PLACE OF RIVETING.
NO HOLES TO PUNCH. NO RIVETS USED.



WELDING SHEET STEEL RANGES.

WHAT THE USERS SAY

¶ One manufacturer welds handles on saucepans. The boy operating the machine puts on 564 dozen handles per day of ten hours, 3 welds each. That's over 20,000 welds per day. Current costs 50 cents per day at 8 cents per K.W. Saves more than 60% over the old method of riveting.

¶ Another manufacturer makes sleds and welds the runners. He says 3 men and a boy are doing the work 17 men formerly did when they used rivets. "He's satisfied."

¶ Still another—a stove manufacturer this time—paid $4.50 per 100 for riveting stove runners. A boy now welds them for 75 cents per 100, and makes better wages than he did when riveting at $4.50. "They are both satisfied."

¶ A wagon manufacturer figures he saves 53% in factory cost when welding hub and sleigh bands. He's another satisfied user.

¶ These are only samples of what others are doing. Is it interesting? It don't cost much to get full information—just give us your address—we'll do the rest.

¶ And by the way, our No. 11 Bulletin gives a lot of information regarding welding. It's free—just ask for it along with a sample of spot welding. And remember

A boy welds 35 ranges per day. A man can only rivet 10 per day.
Costs reduced more than 65%.

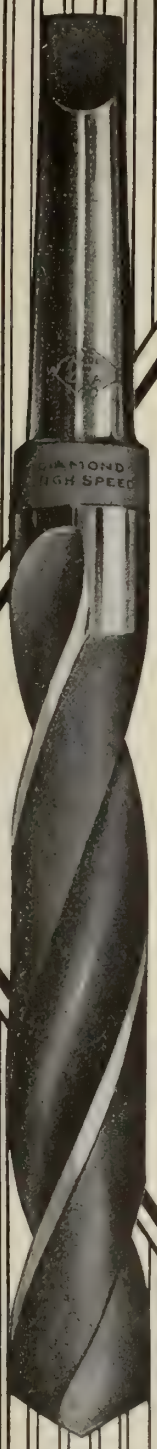
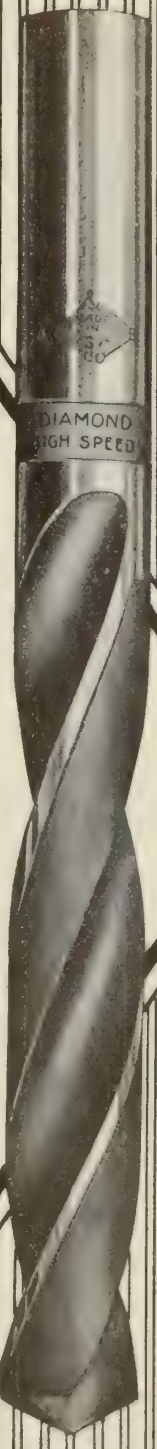
DIAMOND
High Speed Drills





"Diamond" Drills cut faster and cleaner and last longer than most other high speed drills. It is not alone the fact that they are made of Vanadium High Speed Steel (anyone can buy that in the open market) that makes this so, but also the years of experimental work—the processes of manufacture we have perfected, the highly skilled workmen specializing on each detail, and the careful, thorough tests we make of each shipment of steel and of each lot of drills, during the manufacturing process.

We can work with you on a mutually profitable basis, since we make "Diamond" High Speed Drills for every purpose and have studied every known drilling problem. We invite you to make use of the fund of information we have gathered through our testing department.

"Diamond" High Speed Drills carry the W & B Diamond Trade Mark on the shank. Look for it when you buy.

Our latest Catalogue and Price List will be mailed on request. Ask for No. 74 C.

FIRE BRICK *for* Cupolas

¶ The standard Fire Clays by which all other Clays are judged are those of Pennsylvania.

¶ They're the ones from which our Cupola Brick are made.

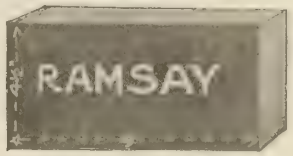
¶ The cost per thousand means nothing unless you know the results the Brick are giving.

¶ Write us for definite examples of how our material affects your melting costs.

HARBISON-WALKER REFRACTORIES COMPANY,
PITTSBURGH, PENNSYLVANIA

FIRE BRICK

AMERICAN and SCOTCH



CUPOLA BLOCKS and all other SPECIAL SHAPES

For Foundries, Blast Furnaces, Rolling Mills, Steel Plants, Cement and Lime Kilns, Glass Plants, Boiler Settings, etc.

IMMEDIATE SHIPMENTS
from our stock in Toronto, or direct from Works.

Steel Castings

Joliette Steel & Iron Foundry, Ltd ---Main Works Building

We make new process converter steel castings, annealed and unannealed.

We also make Chrome Manganese and Nickel Steel Castings.

All sizes, ¼ lb. to 30,000 lbs.

WRITE TO US.

JOLIETTE STEEL AND IRON FOUNDRY, LTD.

Head Office and Foundry - - - Joliette, P.Q.

PROMPT SHIPMENTS

This is something that every foundryman wants when he orders his goods.
We are prepared to give you service, quality, and lowest prices on anything from a DUST BAG to a CUPOLA. If you are not using EUREKA BLACKING you ought to. It's the BEST on the MARKET.
EUREKA CORE COMPOUND (a pitch core compound) of 100% purity, mixes much the same as flour and is as readily taken from the castings. Will not blow and is cheaper than flour.
No. 48 PLUMBAGO, a high graphitic carbon lead, will do the best kind of work, if you are looking for that kind. Write for latest catalog of Polishers' and Platers' Supplies.

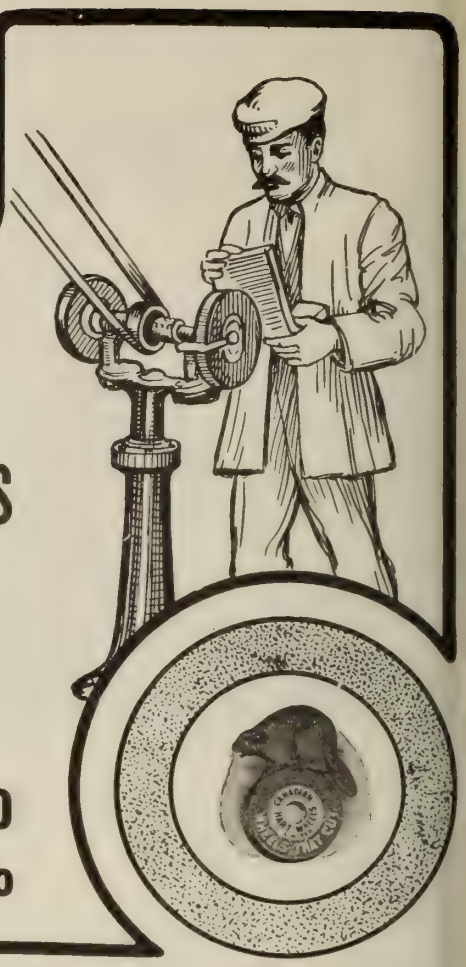
The Daily Grind



The daily grind of mechanics engaged in using abrasive wheels is made much more effective if their machines are fitted with

CANADIAN HART CORUNDUM WHEELS

Our wheels are free and fast cutting, porous, safe, and very durable. Send for our catalogue which describes the various processes used in making Canadian Hart Corundum and Emery Wheels.

WE would like you to understand the new McDougall Lathe. It is a machine of reserve strength and capacity. It can handle your high "speed" steel tools at their maximum speed. You get the benefit.

Note the headstock construction first. See the very wide bearing surfaces and massiveness. The whole machine from headstock to base is like a solid rock. We have done everything that will make this headstock right. It must wear. It must resist strain.

The big bearings are fitted with deep oil chambers and ring oilers. Your lathe is automatically protected against accidental wear and excessive loosening up of the bearings by the operator's omission to oil. Only when you get wear taken care of, have you a headstock which is able to resist strain. Its wide bearings are not only kept automatically in shop perfection, but they take the greatest strain a cutting-tool can give through the work and a spindle in high-carbon steel. The automatic oil device protects the quality of your lathe output by protecting the bearings, so chattering is impossible

Look at the work of a McDougall Lathe some day. You will see a smooth, clean tool-cut, shining and bright. This shows the even feeding of the work from a firm headstock against a firmly-held tool.

The carriage and apron are non-springing. The action of the tool depends on the solidity of bearing given it by the carriage. This carriage is supported by full "V" bearings, and flat bearings as well. There can be no "lost motion" in the carriage, and none at the cutting edge of the tool.

The tool feed reads to thousandths both ways on the compound rest The automatic feed is of the safety type, so interlocked that your mechanic cannot operate both feeds (screw and rod) at the same time.

Here you have a clean cut from a solidly-held tool working against a solidly-held casting, in a lathe so protected by automatic oiling that it always maintains its accuracy and strength. You can adjust this tool to 1-1000 inch. You cannot break tool or work by accidental operation of both feeds at one time. No breakdowns.

Now look at the tailstock. It has a quick-acting sleeve lock device. This permits quick change of work. In addition the tailstock is secured to the webbed and non-springing bed of the lathe by four bolts with top adjustment. Both kinds of tailstock changes are easy and quick—they save workmen's time.

Take another look at this McDougall Lathe. See how well the gap is supported, and how deep the gap is, Though this is a gap lathe, it is as solid as a standard type, because the base is carried under the entire gap opening. Here you have a gap lathe without a single disadvantage of the gap opening and the deteriorated work it often causes.

Get a McDougall Lathe like this in your factory equipment. Its adjustability, speeds, capacity and practicability make it one of the most perfect machine tools. It is particularly economical where a variety of kinds of lathe work have to be done on a single lathe, because it is a quick-change machine.

Suppose you write us your problem. And, to-day, now. The McDougall lathe will raise quality and lower cost.

The R. McDougall Co. Limited, Galt, Canada

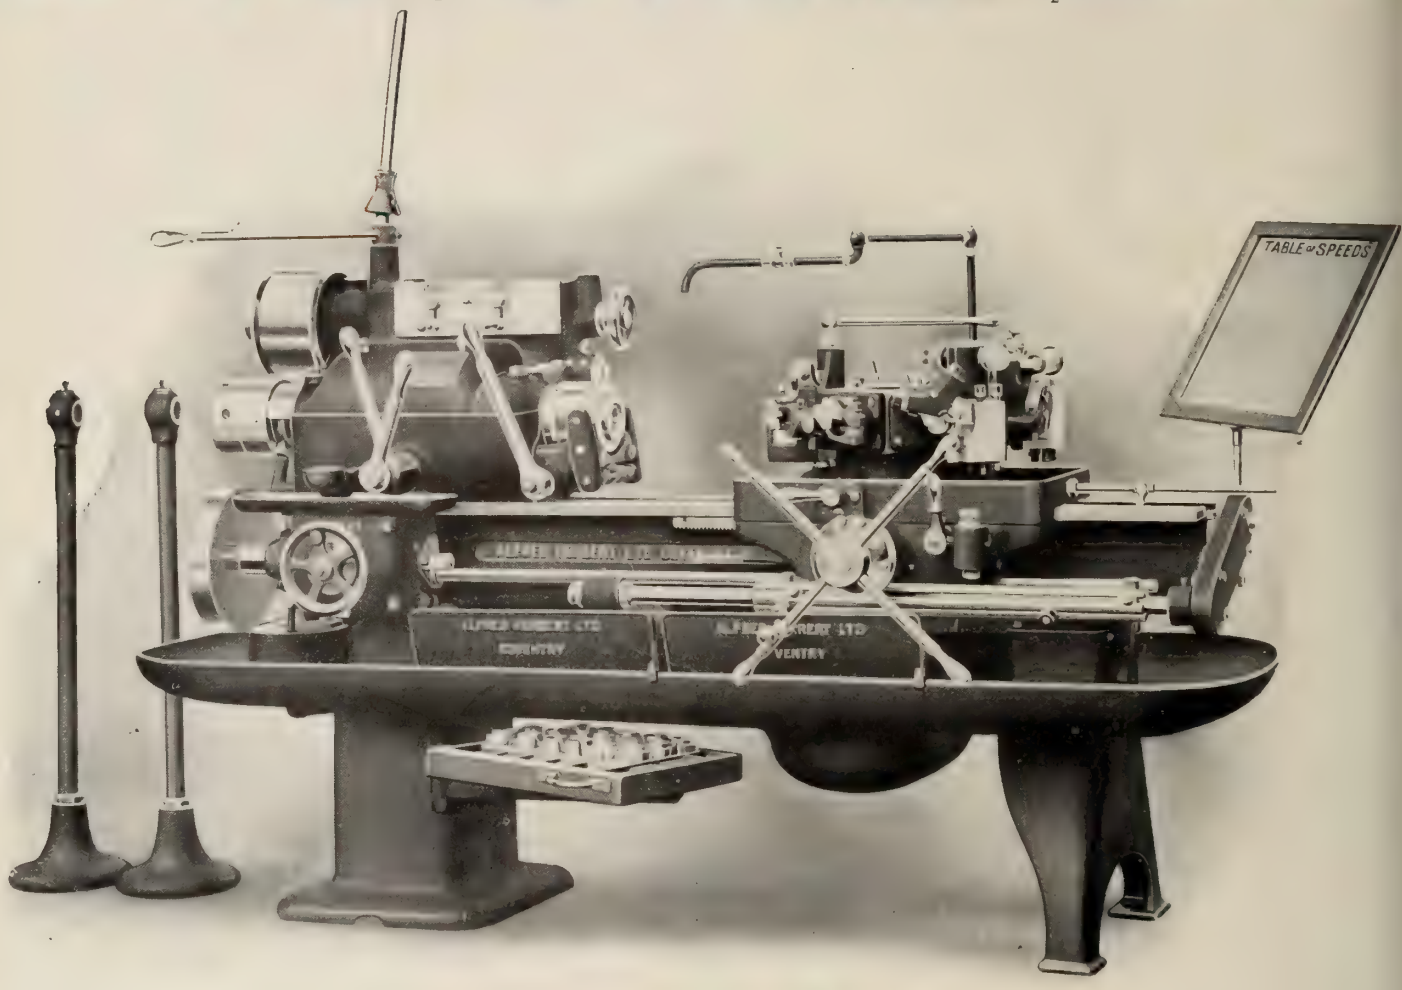
ALFRED HERBERT, Limited

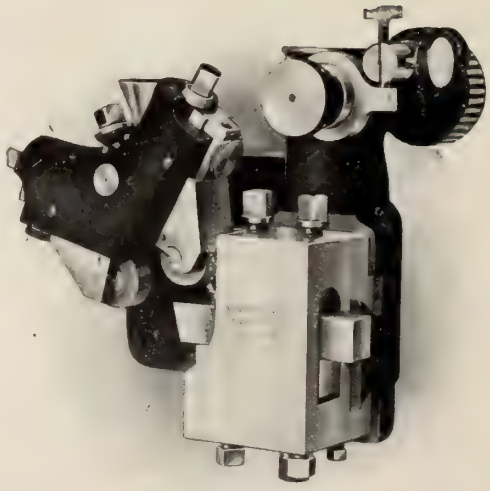
NO. 1 HEXAGON TURRET LATHE—FOR BAR WORK—$1\frac{1}{2}$" x 24".



No. 2 MACHINE, $2\frac{1}{4}$" x 30".

When the work can be put through in quantities of 6 or more at a time, the savings that can be made in labor costs are very great.

We will be pleased to guarantee output on any specified work.



No. 4 MACHINE, $3\frac{1}{2}$" x 42".

Recent Test on No. 2 Machine.

MATERIAL - - -	30-ton Mild Steel.
REDUCTION IN DIA.	$2\frac{1}{4}$" to $\frac{3}{4}$".
SPEED OF WORK -	175 ft. per minute.
FEED OF TOOL -	$10\frac{1}{4}$" per minute.

Catalogue describing latest features mailed on request.

Patent Roller Steady Turning Tool
Two Fitted to Each Machine.

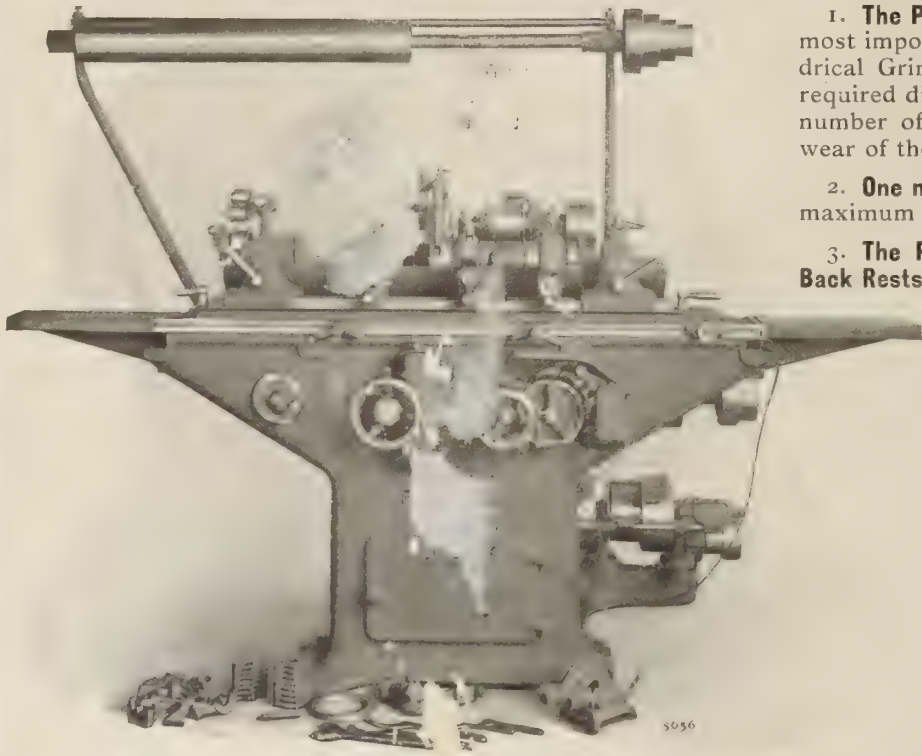
POINTS THAT COUNT FOR RAPID PRODUCTION AND ACCURACY ON THE . .

P. & W. Automatic Sizing Grinder



1. **The P. & W. Automatic Sizing Device,** the most important recent improvement in Cylindrical Grinding Machinery, when once set to required diameter will automatically grind any number of pieces to size, irrespective of the wear of the wheel.

2. **One man can operate two machines** to their maximum capacity.

3. **The P. & W. Automatic Positive Feeding Back Rests** automatically follow up and correctly support the work throughout the grinding operation without yielding.

4. Six instantly obtainable table feeds.

5. Four work speeds are provided.

6. **Downward belt pull on wheel base** eliminates inaccuracy due to upward belt pull.

7. **The new overhead drum drive** dispenses with the usual cumbersome system of countershafting.

8. **Rigidity of construction** throughout eliminates vibration. All features described in "Grinding Machines," sent on request.

The Machine For That Job

—the one you have been handling to a decided disadvantage on a horizontal shaper or a slotting machine. At best the job has been unsatisfactory both as to accuracy of finish and cost of machining. Consider

The New Pratt & Whitney Vertical Shaper

Its Many New and Distinctive Features make this machine fill a long felt need in manufacturing and tool room work.

The Swiveling Ram Head enables work to be completed at one setting and insures perfect parallelism of opposite sides of work.

Ram Bearing Swings on Trunnion, permitting of taper cutting such as die clearances, etc.

New Type of Tool Post dispenses with traditional set screw and allows practically no overhang of tool.

Precision Screws With Micrometer Dials very accurately control the longitudinal and transverse feeds of the table.

Write for full descriptive circular "Vertical Shaper."

Cost Reducing Features

An indestructible spindle bearing made of hardened steel and cast iron.

A head construction that gives more effective pulling power at the spindle than any other lathe built.

A patent "compensating V" that permits four times the bearing area between the carriage and bed found on other lathes.

A carriage in which the tool thrust is taken on a bearing the entire length of the carriage, and which positively will not climb the V.

A double-walled one-piece apron which will last as long as the rest of the lathe.

A quick change gear complete in one unit, giving thirty-six changes with two operating levers.

An offset compound rest which can be used without skinning the operator's knuckles.

The centres set back of the middle of the bed, giving greater swing over carriage and permitting the turning of work up to the maximum swing without the tool overhanging the bed.

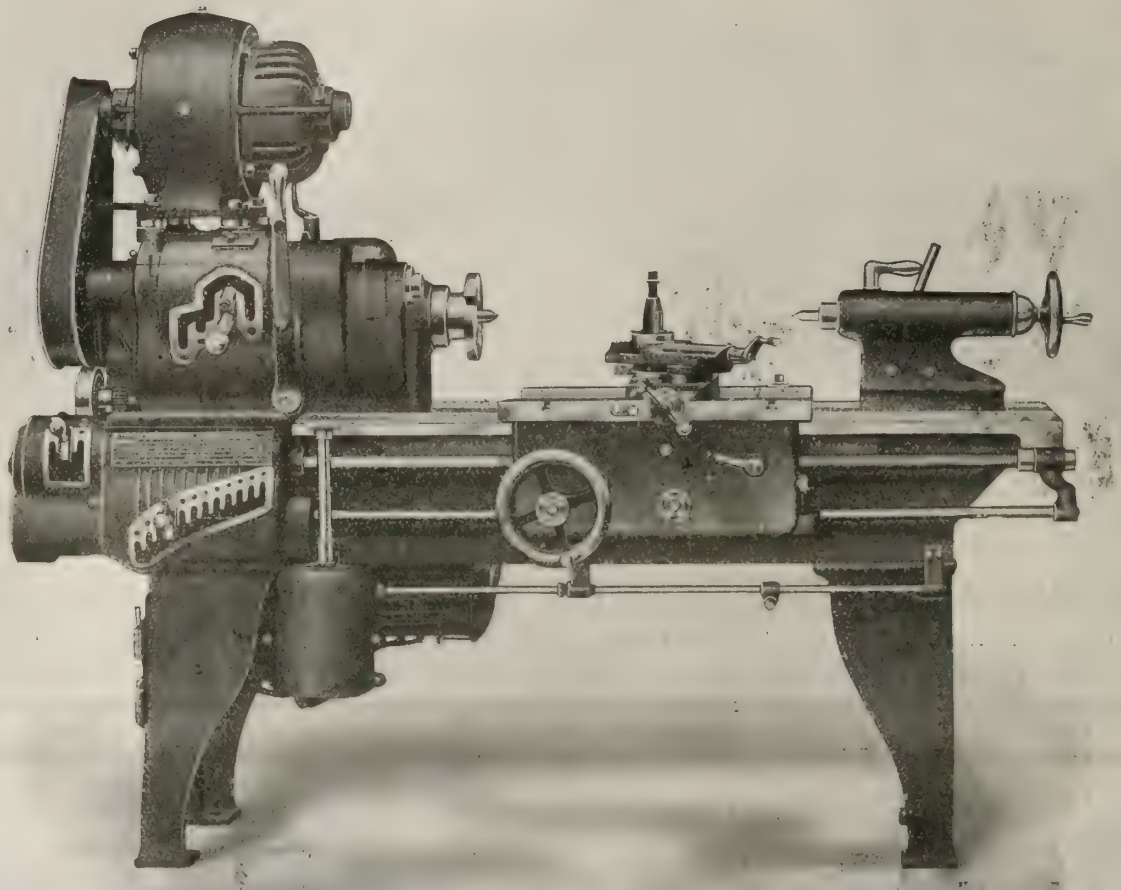
Motor-Driven Machine Tools



A machine with its motive power directly applied as in the above illustration is worth considering. In the first place it can be put in any part of the shop and is not governed in its position by any relation to the main line shafting. Spindle speed regulation by Variable Speed Motor much finer than obtained from countershaft drive.

Load placed upon the power plant is only that called for by work done in machine in contrast to the constant factor of power required to drive long lines of shafting.

We are prepared to furnish all our machines, lathes, shapers and millers with direct motor drives arranged for both D.C. and A.C. motors.

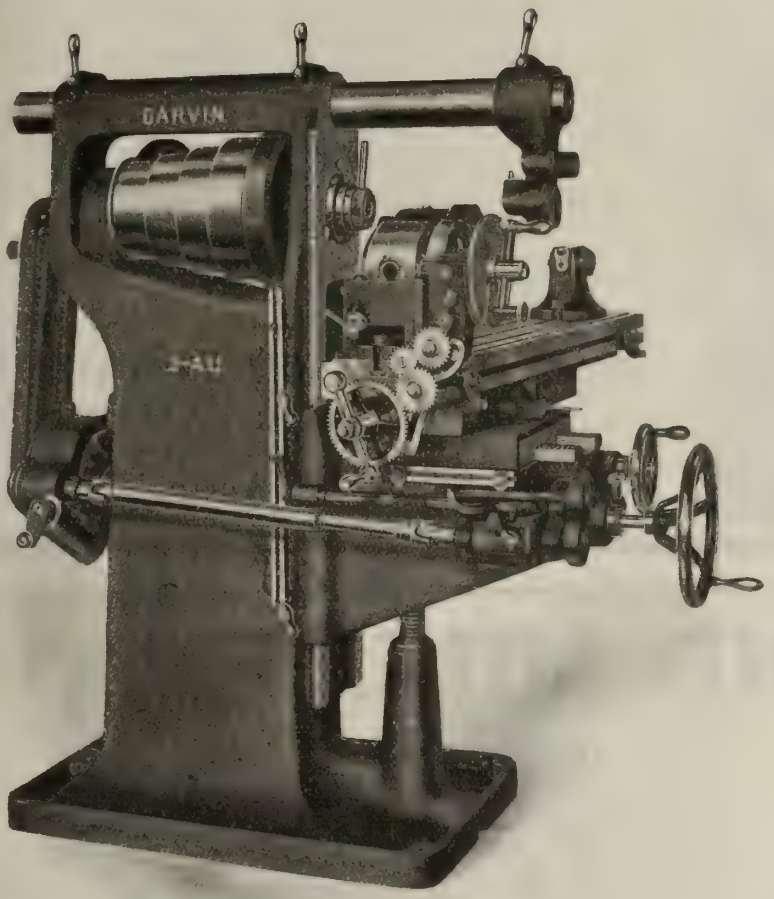
GARVIN No. 2-A (ALL FEEDS) Universal Milling Machine

IS THE MACHINE FOR YOUR TOOL-ROOM——RIGID AND ACCURATE



GARVIN NO. 2-A Universal Milling Machine
(Automatic Feeds in all Directions.)
Use Code.....ANIMU

Power Feed with reverse and automatic trip is provided in all directions, table, in and out and up and down. The feed movements are all controlled by one handle with which the knee, saddle or slide can be started, stopped and reversed. The table has an independent trip handle in addition.

Ten positive Feed Gear Changes are secured, doubled to twenty when back-gears are used. The accelerated feed of table is received, when large diameter cutters are being used and the spindle is running slow. The Feed can be changed while machine is in cut.

Machine is equipped with our Double Geared Dividing Head, our

SOLID TOP EXTENDED (Patented) KNEE

and many other valuable features exclusive to GARVIN Milling Machines.

DIMENSIONS.

Automatic Table Feed	25 in.
Automatic Feed of Saddle	8 in.
Automatic Feed of Knee	18 in.
Dimensions of Table over all	48x9 in.
Taper Hole in Spindle B & S (Positive drive)	No. 10.
Width of Belt required	3 in.
Number of Speed Changes	16
Number of Feed Changes	20
Floor Space required	74x84 in.
Crated Weight	3,500 lbs.

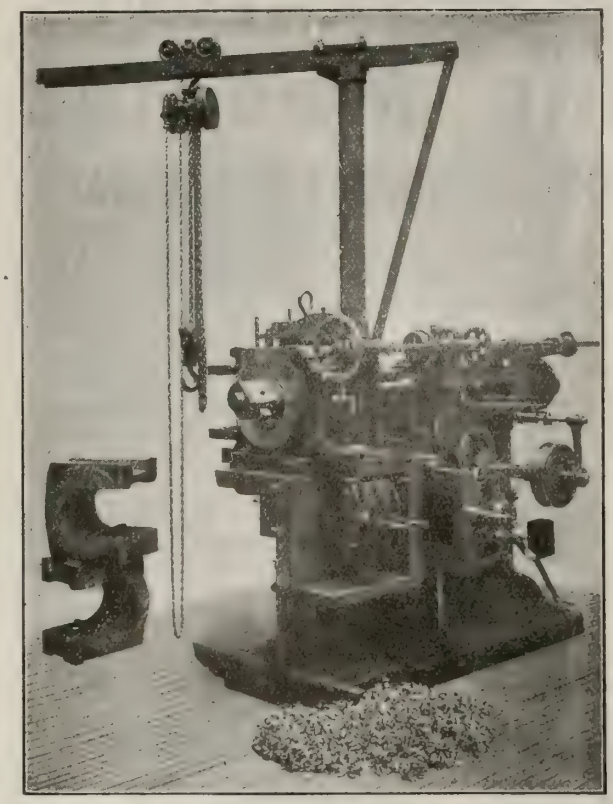
The Morton Draw-Cut Railroad Shaper



This shaper will crown and plane axle boxes, plane the brass shell to fit, and plane shoes and wedges at a saving of from 25 to 40 per cent. over ordinary methods. This machine is also equipped for doing a general line of shaper work.

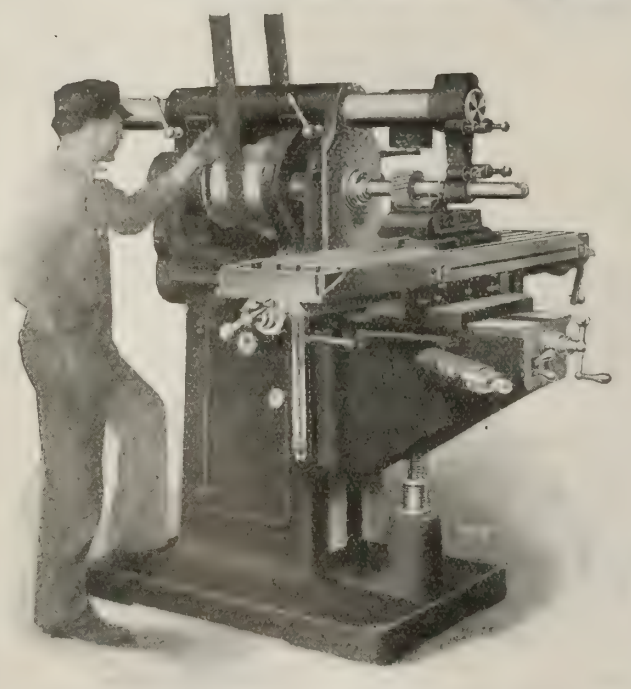
For further particulars address

The Morton Manufacturing Company

MUSKEGON HEIGHTS, MICH.

Also builders of Cylinder Planers and a full line of Draw-Cut Pillar Shapers.

LeBLOND MILLERS



CONVENIENCE OF OPERATION

ON manufacturing operations it is not often necessary to shift the cone belt as the ***Double Friction Back Gears*** give the operator a roughing and finishing speed by merely shifting a lever. But when he does find it necessary he can do so without danger and without the use of a stick or a club, as our back gears are on the right hand side, the left hand side being clear of all obstructions, such as gear guards and revolving back gear quill.

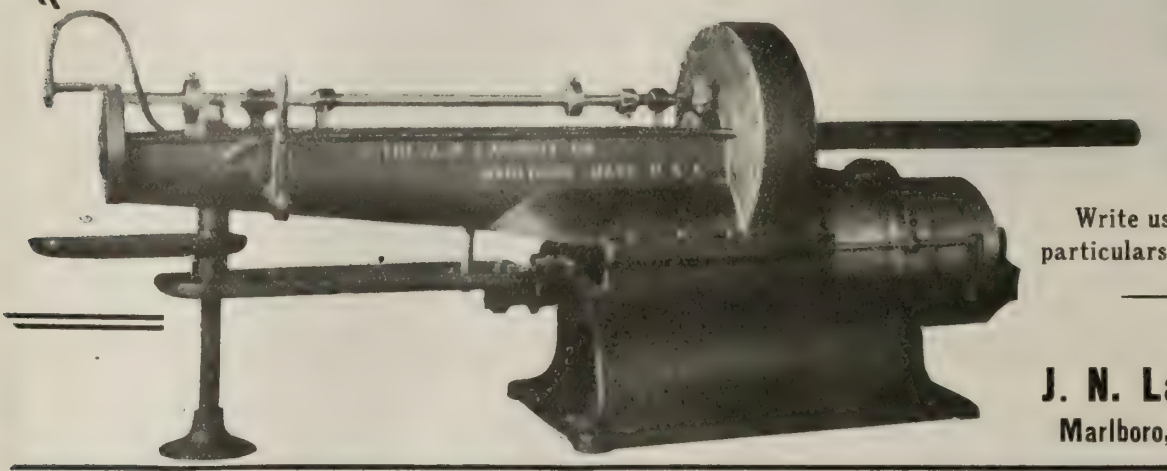
An IMPROVED BROACHING MACHINE

That will be of Great Value to YOUR Shop

It has several improvements over many machines of this type and is capable of doing from the smallest to the heaviest broaching practicable. The construction of this machine is such that friction is reduced to the minimum amount, which gives at least 30 per cent. more pulling capacity than machines with the same power applied. The driving gears of this Broaching Machine are encased, running in grease, which eliminates considerable time in oiling.

As there are no pins or positive clutch in the driving, but simply belts shifting on tight and loose pulleys, the machine can be run at any speed desired without being exposed to injury. The Improved Broaching Machine is provided with an automatic oil pump, flooding the work with oil while being broached, and is also furnished with counter-shaft complete.



It increases quality and quantity of work.

Write us at once for full particulars, if interested.

Save On The Single Piece As Well As The Big Job

The Bullard Vertical Turret Lathe is not alone a manufacturing machine—the very features which make it a good manufacturing machine also reduce the cost of the individual piece.

The Vertical Turret Lathe is ready to save on face plate work of every description within its capacity. Vertical Construction, Ample Power and Rigidity, Multi-Cutting, Quick Speed Change, Centralized Control, Automatic Lubrication—these cost-reducing factors save on the single piece as well as on the big job. It does not keep the foreman on the jump looking for the right job. Nor does it require an expensive special tool equipment for each job.

Investigate. Find out how much less YOUR face plate work will cost done on a Vertical Turret Lathe.

We'll be glad to put some interesting facts and figures before you.

Send for Treatise on Face Plate Work, No. C-15, NOW.

You Can Double Your Output If You Install a

"SPRINGFIELD" Cabinet Turret Lathe

This is one of our latest productions and it contains several new features and improvements that ensure a maximum output at minimum cost. Its accuracy, speed and efficiency cannot be equalled.

The turret is so designed that one slight backward movement of the blades loosens the turret and at the same time withdraws the locking pin; a slight forward movement then produces the partial revolution of the turret for the next tool, and simultaneously locks and tightens it, the entire operation being done in a second or so by one hand.

This lathe is back geared, and has a four-step cone pulley of large diameter.

Do not hesitate. Write us at once for illustrated catalogue on our complete line of lathes and shapers. "SPRINGFIELD SERVICE" is guaranteed to save you money.

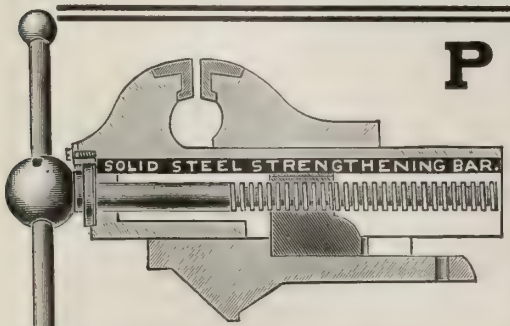
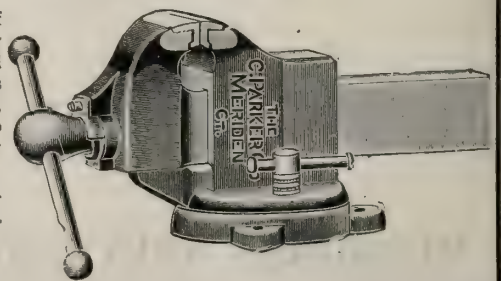
PARKER'S VISES

Are Quick-working, Convenient and Highly Efficient



These vises are made from a mixture of Cast Iron and Bessemer Steel carefully selected, and manufactured by skilled workmen. Our Solid Jaw Swivel Vises have a steel strengthening bar inserted, as shown in cut on left, and, welded into a Casting, renders the slide practically unbreakable.



"PARKER" Vises are the strongest and most durable on the market, and have always given perfect satisfaction. They are guaranteed to be just as we claim.

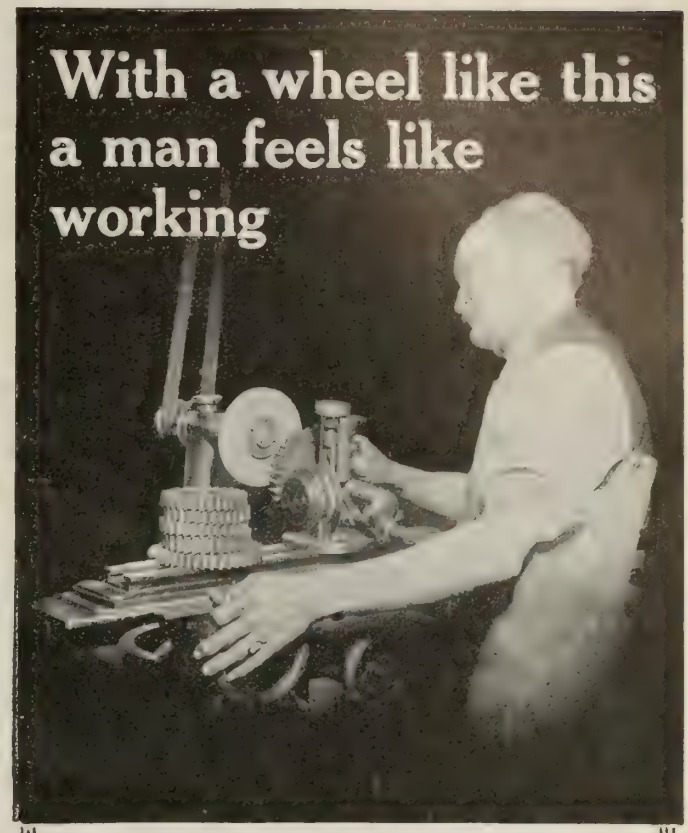
Do It NOW!

Butterfield & Co.

ROCK ISLAND, QUE. DERBY LINE, VERMONT



THERE is such a quiet, easy cutting, business-like way about an Aloxite Wheel, it does its work so quickly, keeps its cutting surface free and clean, and never heats or draws the temper even under heavy cuts—results, more work and better work from you men.

There isn't a material known that cuts steel like Aloxite—take cutter grinding for instance. Illustrated above is a 6-inch Aloxite wheel used for grinding side teeth of a milling cutter — the whole story of the wheel's efficiency is shown in the veteran machinist's expression—he never had a wheel that did the work so thoroughly good—that gave him such perfectly ground cutters in so little time and with so little effort.

Just let your men try out an Aloxite wheel for steel grinding in any shape or form—they'll say just what we say—Aloxite

High Speed Steel Has a Solid Foundation In a Name That Means Something

Cutting speed attained on cast iron: Roughing cut, 140 ft. per minute—finishing cut, 210 ft. per minute.

In NOVO SUPERIOR you secure a materially increased speed over the high speed steels now in use, the highest quality, greatest toughness, longest life (3 times that of any other) and exceptional ability to cut very hard materials. The cutting edge retains its sharpness from 3 to 4 times longer than other high speed steels. Hardens in oil, air or water, and is now carried in stock in our warehouse in all current sizes, flat, squares and rounds; annealed and unannealed.

A Ready-to-Lay Roofing Made of Solid Rock Fibres

National Iron Works, Toronto, Ont., covered with J-M Asbestos Roofing.

J-M Asbestos Ready Roofing is literally made of solid rock fibres. Its base consists of a felt made of stone—pure *Asbestos*. And Asbestos is a natural *rock* formation. Like all rock or stone, practically everlasting. And known the world over as fire-proof. It is the same material that is used to hold the flame in gas grates—the same material of which we make Asbestos Theatre Curtains. You know Asbestos Curtains are required by law, as protection against fire, in the theatres of nearly all cities. So no wonder this Asbestos, or *stone*, roofing never catches fire, even when neighboring buildings burn to the ground.

J-M ASBESTOS ROOFING

Won't Burn—Won't Rot or Decay—Needs no Coating.

We use several layers of this Asbestos or stone felt. And cement them together with genuine Trinidad Lake Asphalt—that wonderful *mineral* cement which, in asphalt pavements, stands the grinding of wheels and the hammering of hoofs for 30 or 40 years. With such indestructible materials as these, do you wonder that J-M Asbestos Roofing often outlasts the building it covers? And do you wonder that this *all-mineral* roofing will never need a single cent's worth of paint to keep it from rotting, decaying or otherwise deteriorating?

Write our nearest Branch for a sample of this curious rock from which J-M Asbestos Roofing is made, also sample of J-M Roofing and Catalog, No. 303.

Why Didn't We Protect Those Windows, too, With Fenestra Sash ?

What *water-tightness* is to an ocean liner—
What *burglar-proofness* is to a bank—
What *strength* is to a sky-scraper—
Fireproofness is to a modern industrial building.

It would seem hardly less logical to handicap the watertight compartments of a ship with frail partitions, to offset the 3-foot cement floors of a vault with a wooden trap-door, or to construct a Singer building on a doubtful footing, than it is to build a modern factory of fire-proof construction, equip it with sprinkler-systems, fire-doors and fire-alarms, and then to demoralize the whole chain of expensive and otherwise carefully planned fire-protection by tolerating the weak link of wooden sash.

Scientific factory construction relegates wooden sash to the day of clapboard walls, plank floors and shingle roofs.

Where else can you reasonably class them ?

FENESTRA FIRE PROOF SASH

glazed with ordinary wired glass is positively the last word in fire-resistance as applied to windows.

Common sense dictates that.

Actual fires have proven it beyond question. In a fire at Stoneham, Mass., in September, a building equipped with FENESTRA SASH was practically surrounded by a burning varnish factory. Reglazed after the fire, the Sash were as good as new. Photographs on request.

Remember, too, that FENESTRA SASH also *light* and *ventilate* a building better than any others. They're made to suit individual needs.

If you are interested in the planning or construction of a building where *light, fresh air,* and *fire protection* are essentials, let us send you our "Fenestra" Catalog.

METALLIC PACKING

Steam pressure, sliding friction and moisture make it difficult to properly lubricate piston and valve stem rods, hence a self-lubricating metal like Magnolia naturally proves superior to other metals for packing rings. We recently published some splendid letters from Engineers on that subject, and here is another fine letter:

UNITED STATES ENGINEER DEPARTMENT
U.S. Dredge "Wallowa."

Riparia, Was., October 24th, 1911.

GENTLEMEN,—I use Magnolia Metal for high pressure steam packing on the main rods of the propelling engines. These engines have a piston speed of 150 feet per minute; diameter of rod, 3 inches; steam pressure, 225 lbs. per square inch. Four rings or eight pieces, beveled Magnolia metal rings, constitute the packing for each rod. I had a great deal of trouble with packing on the main rods, before using Magnolia Metal, with different kinds of babbitt metals. The packing would melt or burn and crumble. I have at different times, when renewing packing, taken out from 30 to 40 pieces from each set, out of one stuffing box. Since using Magnolia for the rings, I have had no trouble whatever with the packing, and after the rings got conditioned to the rods no steam leaked by. To-day I examined the packing rings and found them in as perfect condition as when I put them in four months ago, with hardly any sign of wear to them, and they look good for years of hard service. I cannot speak too highly of Magnolia Metal.

Yours truly, JOHN OWRE,
Steam Engineer on U.S. Dredge "Wallowa."

SPECIAL OFFER

PRACTICAL ENGINEER POCKET BOOK, 680 pages, over 2000 subjects. Price 40c post paid. We do not aim to make a profit on these books. We buy them in large quantities as an advertising medium and give Engineers benefit of low price. They are highly spoken of by Engineers. Address Montreal office.

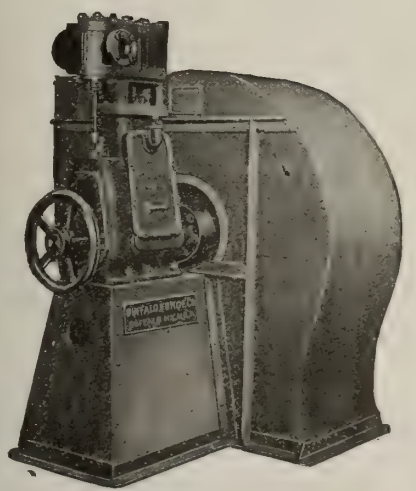
"Buffalo" Fan System of Mechanical Draft



Buffalo Automatic Engine driving Steel Plate Fan for Mechanical Draft

The most scientific and up-to-date method of increasing boiler plant efficiency

Gives every boiler plant the widest possible range of capacity, with flexible, positive and instantaneous control. Every sudden demand for steam is easily and promptly met. Combustion is maintained at highest efficiency, while low grade fuel can be used to great advantage.

The automatic engines used with the fans are especially adapted to service requiring a high degree of efficiency and reliability with a minimum of attention.

Installations of this system are to-day in successful use in gas, electric and power plants, schools, colleges, public buildings, hotels and industrial plants of all kinds.

Their ready adaptability to every condition makes their use standard in the modern boiler plants.

pumping machinery are largely due to the fact that for many years we have manufactured Hydraulic Machinery of all descriptions. We are therefore able to build pumps which are properly designed and adapted to every-day use. This is of the greatest importance in a first-class pump, for the usefulness of an engine may be lost if the pumping machine is badly designed.

You will get all these important features when you purchase a "FAIRBANKS-MORSE" pump.

Let us solve your pump problems.

Herringbone Gears---Features and Applications*

By Percy C. Day, Milwaukee. Wis. **

This paper relates especially to a type of herringbone gears, known as Wuest gears, after the name of the inventor. The distinctive feature is that the teeth on one side of the centre line of the face are stepped half the pitch ahead of those on the other side, so that they do not meet at a common apex at the centre line, as in the ordinary herringbone type. This arrangement makes it possible to hub the teeth by the aid of special machinery, and to secure great precision.

THAT the helical principle in toothed gearing is ideal from a theoretical point of view is well known. From a practical standpoint herringbone gears have been less satisfactory than straight-cut spur gears because, until recently, no method was devised for producing them with the requisite speed and accuracy. Within the last six years a method has been found and developed, in England, to a high degree of perfection. Herringbone gears made by this method are called Wuest gears, after the name of the inventor, and can be produced with even greater accuracy than cut gears of the spur type (Figs. 1 and 2).

The distinction between these gears and those of the ordinary herringbone type is that the teeth of the former, instead of joining at a common apex at the centre of the face, are stepped half the pitch apart and do not meet at all. This arrangement of the teeth does not affect the action of the gears, but it facilitates their commercial production and admits the use of precision methods in their manufacture. The utilization of power constantly calls for means to transmit rotary motion from one axis to another and to transform the speed of rotation. While there are many ways in which such transmissions and transformations may be produced, the merits of all of them must be judged from the following standards: (a) reliability and freedom from wear and tear; (b) economy of outlay; (c) mechanical efficiency; (d) compactness; (e) evenness of transmission, absence of shock, jar or vibration; (f) absence of noise. The order of merit may change with different applications, but the same standards obtain for all transmissions. The various methods employed are so well known that they need no discussion here. Let it suffice to say that the spur gear, which satisfies only the first four conditions is used to such an extent that all other appliances are relatively unimportant.

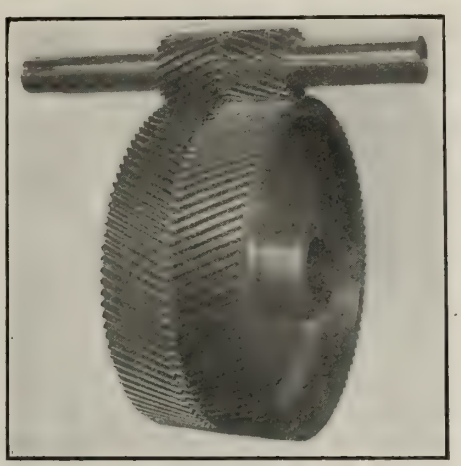

Fig. 2.—Gear and Pinion for 200 H.P. Turbine, to Run at 5,000 ft. per min.

Action of Spur Gearing.

The aim of all designers of gearing is to transmit rotary motion from one axis to another in a perfectly even manner without vibration of angular velocity. Let us consider the action of a straight spur pinion driving a gear. There are three distinct phases of engagement:

a—First phase.—The root of the pinion tooth engages the point of the gear tooth.

b—Second phase.—The teeth are engaged near the pitch line.

c—Third phase.—The point of the pinion tooth engages the root of of the gear tooth.

Let us assume that the teeth are accurately cut to involute form so that if the pinion moves with even angular velocity it will produce corresponding evenness of motion in the gear. Also that the pinion has sufficient teeth to allow the engagement of successive teeth to overlap.

Figs. 3 to 5.—Diagrams Showing Tooth Pressures and Angle Necessary for Continuity of Action.

* Presented at the annual meeting, Dec., 1911, of the American Society of Mechanical Engineers.

** Engineer with the Falk Co.

At the beginning of the first phase, while the load is carried near the point of the gear tooth, that tooth is subjected to a maximum bending stress along its whole length. During the first phase, the portion of the pinion tooth near the root is sensibly sliding over the outer portion of the gear tooth; that is to say, two metallic surfaces of small area are sliding under heavy compression.

The action during the second phase more nearly approaches ideal conditions. The teeth are engaged near their respective pitch lines and very little sliding takes place.

During the third and final phase, the pinion tooth is subjected to a maximum bending stress, while the tooth surfaces again slide over each other, this time with the outer portion of the pinion tooth engaging the gear tooth near its root.

The point to be noted is that while those portions of the mating teeth which are near the pitch lines transmit the load with rolling contact, those which are more remote have to transmit the same load with sliding contact. The inevitable result is that the points and roots of all the teeth tend to wear away more rapidly than the portions near the pitch lines, so that the involute tooth curves, necessary to the preservation of even angular velocity, lose their form and the motion becomes uneven. It may be suggested that the sliding action can be got rid of by shortening the teeth so that they engage only the phase of rolling contact. This has been tried with a certain measure of success in the stub-toothed gear, but it cannot be carried far enough without curtailing the arc of contact so that continuity of engagement is lost, thereby introducing more serious trouble than that which it is desired to avoid.

Distortions of gear teeth from involute form, whether due to inaccurate cutting or subsequent wear, give rise to all kinds of trouble. The average angular velocity may be uniform, and yet the passage of each pinion tooth through its brief engagement with the mating gear may be accompanied by successive retardation and acceleration which, though small in itself, takes place in such a short interval of time that it may cause interacting stresses many times greater than the average working load on the teeth. These internal stresses are very difficult to deal with, because they are indeterminate. They cause noise, vibration, crystallization and fracture.

Action of Herringbone Gears.

Herringbone gears completely overcome all these difficulties, but only when they are accurately cut. The writer will first assume the accuracy and describe the action, afterwards he will endeavor to show how the system under discussion has special features which insure the production of accurate herringbone gears on a commercial scale. If we take two exactly similar pinions with straight teeth and place them side by side on one shaft, with the teeth of one pinion set opposite the spaces of the other, then we have what is known as a stepped-tooth pinion. If this pinion is meshed

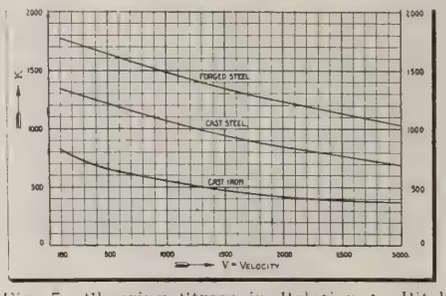

Fig. 7.—Shearing Stress in Relation to Pitch Line Velocity.

with a composite gear made up in a similar manner, the action is modified so that there are always two phases of engagement taking place simultaneously. Such gears are commonly used for rolling mill work, because they stand up to heavy shocks better than the plain type. Still better action can be secured by assembling a number of narrow pinions with the last of the series one pitch in advance of the first and the others advanced by equal angular increments. As a practical proposition, however, gears made on these lines would be costly and difficult to produce.

The helical gear is the logical outcome of the stepped gear carried to its limit, and built up from infinitely thin laminations. Since the steps have merged into a helix, there must be a normal component of the tangential pressure on the teeth, producing end thrust on the shafts. To obviate end thrust, the helical teeth are made right-hand on one side of the face and left-hand on the other. Such gears, with double helical teeth, are known as herringbone gears. The fundamental principle of the action of herringbone teeth lies in the circumstance that all phases of engagement take place simultaneously. This holds good for every position of pinion and gear, provided only that the relationship between pitch, face width, and spiral angle is such as will insure a complete overlap of engagement. Since all phases of engagement occur together, it follows that the load is partly carried by tooth surfaces in sliding contact and partly by surfaces in rolling contact. The result is curious and interesting.

Those portions of the teeth farthest from the pitch line, which engage with sliding action, tend to wear away more rapidly than the portions nearest the pitch line, but the pitch line portion is always carrying part of the load, and the effect of wear on the ends of the teeth merely tends to throw more load on the center portions; in other words there is a tendency to concentrate the load near the pitch lines. The ends of

	RELATIVE $\frac{nh}{ns}$	= 1.19	2.0

Fig. 6.—Relation of Driving Pressure to Angle of Teeth.

the teeth, instead of wearing away to an ever-increasing extent from their original involute form, are relieved of some of the load from the moment that wear commences to take place. As soon as the load on these ends has been partially relieved and transferred to the middle portion, the wear becomes equalized all over the teeth and they do not tend to distort further from their original shape.

Fig. 8.—Gear and Pinion for 500 H.P. Marine Turbine.

It is quite clear that an unmeasurable amount of wear on the tooth ends will be sufficient to relieve them of all the load, so that the distortion from original form will be practically nothing. The minute extra wear that does take place at the ends is only the amount necessary to transfer such proportion of the load near the pitch lines that the wear is equalized all over the surface of the teeth, those portions in sliding contact carrying less than those in rolling contact. Thus the teeth keep their involute form and motion is transmitted from pinion to gear in a perfectly even manner, without jar, shock, or vibration. Although herringbone teeth may not be intrinsically stronger than straight teeth, the elimination of all shock and indeterminate internal stresses renders them capable of dealing with far heavier transmitted loads. The concentration of the major portion of the load on the parts of the teeth in rolling contact eliminates friction to a marked extent.

Since all phases of engagement occur simultaneously, the transference of the load from one pinion tooth to the next takes place gradually instead of suddenly. This is the second principle of herringbone gearing, and may be termed continuity of action. In straight gears the continuity of action is a function of the number of teeth in the pinion. Straight pinions with less than twelve teeth are seldom made, and more than that number must be used if the drive is to be even moderately satisfactory. In herringbone gears, continuity depends on the relationship between the face width and the number of teeth in the pinion. Pinions with as few as five teeth have been used with success by merely increasing the face width to suit such extreme conditions. This feature, which is peculiar to herringbone gears, has made practical the adoption of extremely high ratios of reduction hitherto considered impossible.

The third principle of herringbone gearing is that the bending stress on the teeth does not fluctuate from maximum to minimum as in straight gears, but remains always near the mean value. This feature is of special importance in rolling-mill driving and work of a similar nature.

To summarize the foregoing arguments :—The action of herringbone gears is continuous and smooth ; there is no shock of transference from tooth to tooth ; the teeth do not wear out of shape ; the bending action of the load on the teeth is less than with straight gearing and does not fluctuate to anything like the same extent ; the gears work silently and without vibration ; the phenomenon commonly termed back-lash is absent ; friction and mechanical losses are reduced to a minimum ; herringbone gears can be used for higher ratios and greater velocities than any other kind. These advantages are limited to gears which can be produced with a degree of accuracy which will insure the practical realization of the principle involved.

The Production of Herringbone Gears.

Herringbone gears may be produced in a variety of ways which differ from each other as widely as the character of the product. Until a few years ago all gears of this type were molded. The limitations of molded gearing are analogous to those which would be experienced if a journal were set to run in a molded bearing. Just as the bearing would touch the shaft only in spots, so molded gears utterly fail to give the intimate contact all along the teeth which is necessary to secure the realization of true helical gear action. It is obvious that if the teeth touch only in a few high places, they will be subjected to all the evils of shock, stress and inequality of motion which it is desired to avoid.

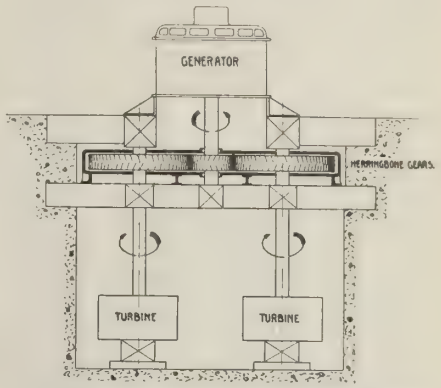

Fig. 9.—Diagram of Gear Connection Between Hydraulic Turbines and an Electric Generator.

If the gears are particularly well molded, some mitigation may be expected when they become well worn, but initial wear is accompanied by a departure from correct tooth shape. For slow speeds, a well-molded helical gear is no better than a straight gear with cut teeth, and for high speeds it is not as good. The

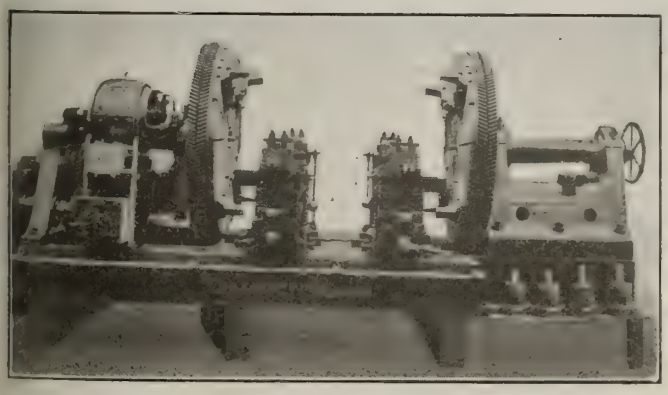

Fig. 10.—Tire Turning Lathe with Herringbone Gears.

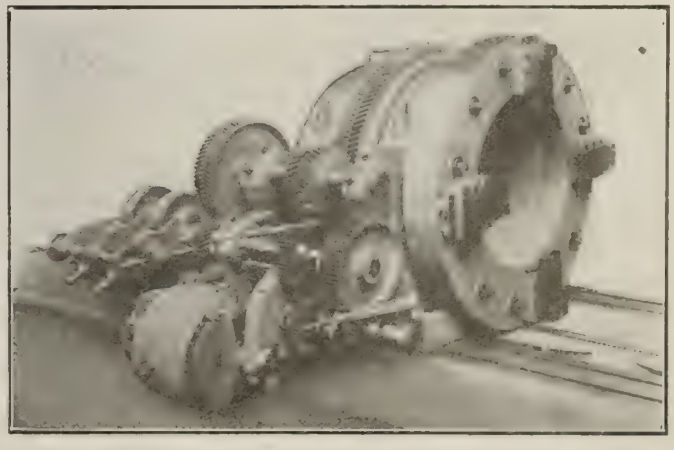

Fig. 11.—Gun Boring Lathe with Herringbone Gears.

natural smoothness of helical action does no more than compensate for the inaccuracies of tooth form and spacing. The modern herringbone gear must have cut teeth if its advantages are to become real.

Cut herringbone gears may be broadly divided into two classes, two-piece and one-piece gears. The difficulty in the way of cutting double helical teeth in a single blank gave rise to the two-piece variety. The same methods of cutting may be used for both kinds. The disadvantages of the two-piece type are fairly obvious. There is the expense of two complete gears, the difficulty of assembling the gears so they are in accurate register with each other, and the necessity for very complete fixing if they are to perform hard service without getting out of register. High ratios, perhaps the strongest feature of the one-piece type, are not within the scope of the built-up gear, because the pinions must be assembled on a separate shaft and the pitch line must be far enough from the surface of the shaft to allow room for the necessary bolts or rivets used in fastening the two portions together. The one-piece pinion, however, may be cut solid with its shaft, so that its pitch diameter need be but very little larger than the latter. The known methods of cutting helical gears may be divided into four classes : (a) milling by formed disc cutters ; (b) milling by end mills ; (c) generating by shaping or planing methods ; (d) generating hobs.

Milling by formed disc cutters is unsatisfactory because, in addition to the usual errors of step-by-step division, there is the difficulty of making the cutters to the normal tooth shape with sufficient accuracy to insure correct circumferential shape for the gears cut. This difficulty is increased by reason of the fact that a disc cutter cannot cut its own shape in a spiral groove. Let it be noted that the cutters must be formed empirically, that their number must be very large to meet the requirements of a general gear business, and that the accuracy of each gear turned out depends on the combined efforts of the toolmaker and draftsman who produced the cutter. Worst of all, two different cutters must be used for a gear and pinion. This method will produce indifferent herringbone gears which may be built up with teeth in register or made in one piece with staggered teeth.

The use of end-mills is open to all the objections given with regard to disc cutters, with the single exception that the cutter does leave a fair approximation to its own shape in the groove which it cuts. The end-mill has a host of disadvantages peculiar to itself which render it even less efficient than the disc cutter for general work. In the first place, it is a small tool with very little wearing surface and no capacity for dissipating the heat generated at its cutting edges. The great variation in diameter between point and base renders it difficult to arrive at a cutting speed which will satisfy the conditions at both ends of the cut. When used for any but the largest pitches, outside the range of general gear practice, the mills quickly become clogged with cuttings, overheat and burn. A burnt end-mill, clogged with cuttings, produces a wider groove than a good mill. This is a fruitful source of spoiled work. To complete one fair sized gear by the end-mill process requires quite a number of cutters. This not only makes the expense heavy, but must necessarily result in an inaccurate gear.

Every cutter used must be formed to gage and hardened. After being hardened, it will run out of true a little in most cases, thereby cutting a shape different from that for which it was designed. In end-mill gears it is not merely a case of getting accurate conjugate tooth shapes in gear and pinion made with different cutters, but the teeth in a single gear may have a dozen different shapes. The process is so slow that it cannot compete with other methods, quite apart from the doubtful quality of the gears produced.

End-milled herringbone gears are usually made in one piece with the teeth joined at the center. Since the cutter is shaped to the normal pitch, it follows that, in changing over from right to left hand helix, it leaves a thick wedge in the center of the face that must be removed by a subsequent operation. The teeth of end-milled herringbone gears do not bear over the center portion.

Generating processes by the shaping and planing types, while successful for straight-cut gears of relatively small size, are not used to any extent for large diameters or heavy pitches. The reason for this may be found in the nature of such processes. The gear blank is required to make a quick angular movement after each stroke of the cutting tool and to come to rest again before the next stroke. Such methods are difficult to apply to large gears on account of the inertia of the gear blank and its support and the consequent difficulties of controlling the short intermittent movements. These difficulties are much increased when such methods are applied to cutting helical teeth because the blank must make definite and rapid angular movements during each stroke in addition to the motion between strokes. No machine has been devised which will satisfactorily deal with the problem on these lines.

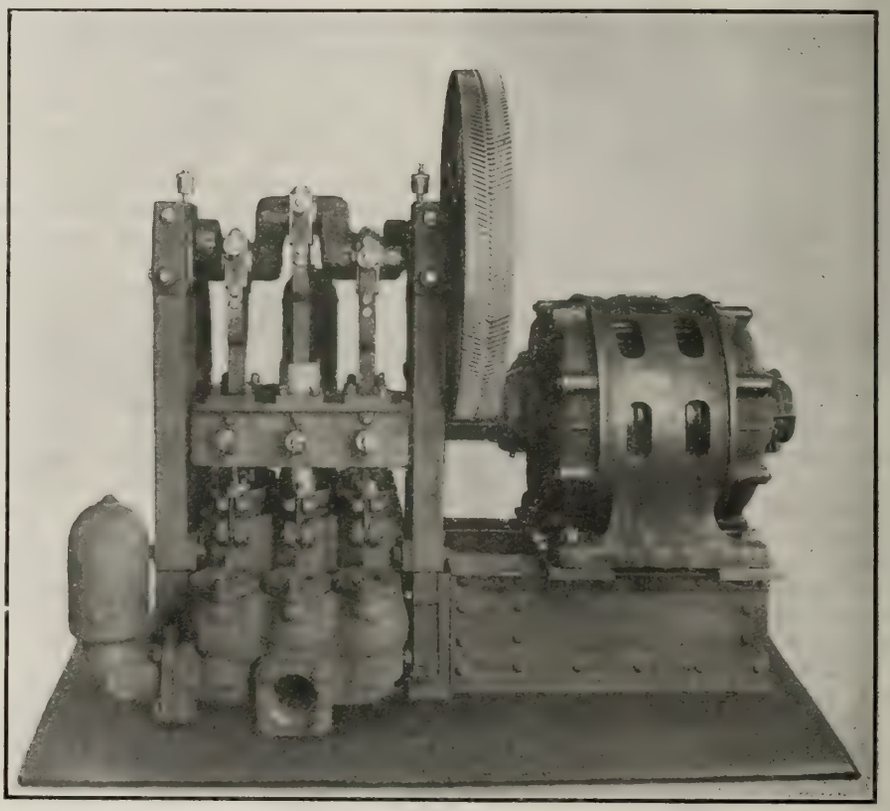

Fig. 12—Herringbone Gears Applied to Electrically-Driven Triplex Pump.

The hobbing process as supplied to straight-cut gears has proved so successful as to arouse a storm of adverse criticism from those who are interested in other methods of gear production. It is not difficult to understand why this process has sprung into prominence in a comparatively short time. It is essentially a rational process. The shape of the teeth is generated from spiral hobs,

the threads of which are cut to a plain rack section. There is nothing empirical about a hob; it is a straightforward thread cutting, gashing and relieving proposition. One hob will cut any gear or pinion of one pitch. This feature alone eliminates a host of errors which are characteristic of gears produced by milling methods. The hob revolves continuously while cutting, as does the gear blank. The feed is also continuous. There are no cutting and return strokes, no intermittent starting and stopping of gear blanks, as in other generating processes. These features do not necessarily insure the production of accurate gears, but they offer greater facilities to the designer for the achievement of the desired result. The hob is a substantial tool with plenty of wearing and cooling surface, it can be made to stand up to very fast production and to last for a long time. The continuous nature of all motions used in hobbing a gear blank enables this process to be used for the production of the heaviest gears, there being no limitations such as are encountered in other processes. The limit to the size of a hobbing machine is set by the dimensions of the largest gears which are required in sufficient quantities to pay for the investment. There are no technical limits whatever. Nevertheless there are some slight defects in the hobbing process as applied to the production of straight-cut spur gears. A hob is a worm thread, and as such must have a spiral angle depending on the relationship between the pitch of the thread and the diameter of the hob. A straight-cut gear has no spiral angle, hence the spiral hob must be inclined, more or less to bring the cutters in line with the tooth spaces to be cut. In order to cut correct teeth, the axis of the hob should be perpendicular to the axis of the gear blank. In such case the hob will generate involute teeth if its threads are cut to the same axial section as the straight-sided parent rack for the required pitch. Since the hob must be inclined to cut a spur gear, the teeth are not generated from the axial or rack section, but from a diagonal section. The axial pitch of a hob for cutting spur gears is not the same as the pitch of the gears which it cuts. The normal pitch of the hob threads must be the same as the gear pitch.

Hobs for cutting straight spur gears are usually made of large diameter to reduce the spiral angle and consequent errors of tooth form to a negligible minimum. As a natural consequence, such hobs have only one thread, while their large diameter requires a slow speed of rotation to keep the cutting speed within proper limits. The effect of this is that the blank revolves very slowly, and a coarse feed must be used to keep up the output. It is one of the peculiarities of each hob action that only one tooth of the hob puts the finishing touch to the bottom of a tooth space once in each revolution of the gear blank. If the feed is coarse, there will be noticeable feed marks and roughness in the gear teeth produced. A coarse feed used with a hob of large radius throws severe stresses on the hob arbor and its supports. The necessity of a swivel motion on the hob slide, to enable straight spurs to be cut with hobs of varying spiral angle, compels the use of a hob drive which passes through the pivot. It is almost impossible to design such an arrangement without undesirable restriction in the dimensions of driving gears and shafts combined with excessive overhang of the hob arbor in relation to its supporting slide.

true rack section of the hob, while the linear pitch of the hob is the same as the circular pitch of the gear which it cuts. The hob axis is fixed and the hob can be supported on a rigid slide with the minimum of overhang. There is no restriction to the size and strength of the gears and shafts used to drive the hob.

Wuest Herringbone Gears.

It has been explained that the teeth of the Wuest gears are so designed that those on the right and left-hand sides of the gear are stepped half a space apart and do not meet at a common apex at the center of the face, as in the usual type of herringbone gear. It has often been argued that the ordinary herringbone tooth is stronger than the Wuest tooth, because the latter lacks the support given by the

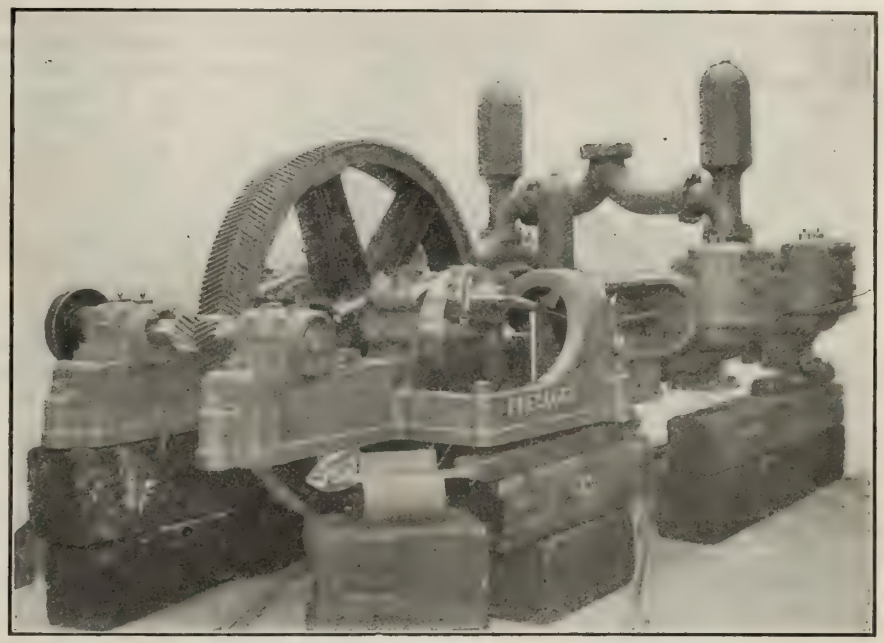

Fig. 13.—Gear-Driven Horizontal Pump, Gear Ratio 12¼ to 1.

The general want of rigidity about most hobbing machines used for the production of spur gears, is traceable to the above causes. Rational critics of the hobbing process have based their objections on these features.

The hobbing process properly applied to the production of herringbone gears has none of the disadvantages, incidental to its application to spur gear cutting, which have been shown to lie in the necessity of inclining the hob axis. Since a helical gear and a hob must both have a spiral angle, it is only necessary to make the thread angle of the hob the complement to the corresponding angle of the gear teeth to secure the advantages of perpendicular fixed axes. These are of great practical value. Since the hob axis is always perpendicular to the axis of the gear blank, it follows that the teeth are generated from the axial and

junction of the teeth at the center. This argument would be sound if gear teeth were ever stressed to anywhere near their breaking point, but it has been found in practice that considerations of wear so far outweigh those of mere breaking strength that a gear which is designed to give reasonable service will carry anywhere from ten to twenty times the working load without fracture. A point of vastly greater importance is that the stepped form will wear more evenly under extreme loads than the ordinary type. The reason for this is shown in Figs. 3 and 4. The resultant tooth pressure is always normal to the teeth and tends to bend them apart. The stepped form offers a uniform resistance along its whole length, carrying the load from end to end, Fig. 3. The teeth of ordinary herringbone gears tend to separate more at

the sides than near the supported centre, causing the load to be concentrated toward the centre, Fig. 4.

Any system of gearing, if it is to be generally applied, must be interchangeable. The variable features of involute spur gear teeth are limited to the pressure angle, addendum and dedendum. In a herringbone-gear system, we must have besides, uniformity of spiral angle and relative position of the right and left-hand teeth. The standards which have been adopted for Wuest gears are the result of experience gained in Europe during the last six years. The spiral angle of the teeth is about

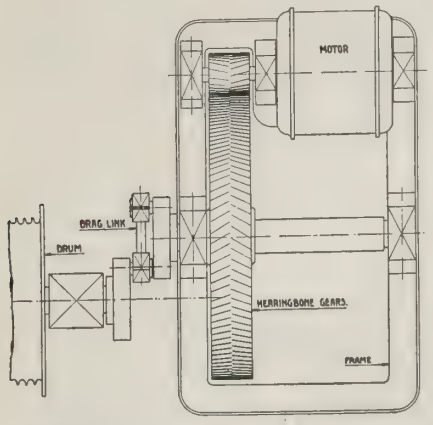

Fig. 14.—Electrification of Mine Hoist, Formerly Steam Driven.

23 deg. with the axis. The choice of this angle is controlled by a number of considerations, the most important from the user's standpoint being that the angle must be sufficient to allow the engagement of successive pinion teeth to overlap within a reasonable face width. Once this condition is satisfied, there is no advantage in an increase of spiral angle, while there are disadvantages in the use of steep angles. It was necessary, before choosing a definite spiral angle, to determine what constitutes a reasonable face width for this class of gearing.

Since the nature of the action eliminates shock, it follows that the pitch required for given conditions will be much finer than would be chosen for spur gears. On the other hand, the face width will not be less, because there is as much necessity for wearing surface with one kind of tooth as with the other. Spur gears are usually made with face width equal to three or four times the pitch. Herringbone gears may conveniently have a face width equal to six times the pitch not because the width of this type need actually be greater, but by reason of the pitch being proportionately less.

Starting with a width equal to six times the pitch, and allowing once the pitch as the non-bearing portion in the centre, there remains two and one-half times the pitch available for the teeth on each side. To ensure continuity of engagement under all ordinary conditions, each tooth is inclined so as to cover an advance of once the pitch within its length. The angle of 23 deg. satisfies the requirement, see Fig. 5. There are a few cases where an angle less than 23 deg. would be sufficient, a steeper angle is only needed if the available face width has to be unduly restricted. Neither of these extreme conditions should influence the choice of angle for an interchangeable system best adapted for general use.

There are other good reasons why a moderate spiral angle is to be preferred. In all spiral gears the pressure acts in a direction normal to the teeth and is the resultant of the tangential (driving) and axial pressures. The normal pressure becomes greater in proportion to the useful driving pressure as the spiral angle is increased, while the available normal tooth section becomes less, Fig. 6. When the spiral angle is sensibly steeper than the angle of repose for the materials in contact, there is a tendency for the teeth to bind with a wedge action. Herringbone gears with abnormally steep spiral angles show loss of efficiency and increased wear from this cause.

The pressure angle which has been adopted for standard gears is 20 deg. The teeth are shorter than the usual standards, with addendum 0.8 and dedendum 1.0. These standards of tooth height and pressure angle have been adopted after systematic trials and experience extending over several years of regular manufacture. The high ratios used with these gears call for an average pinion diameter which is less than that used with straight spur-gears for similar duty. The teeth are generated by hobs, and the short adendum combined with wide angle gives satisfactory tooth shapes, without undercutting of

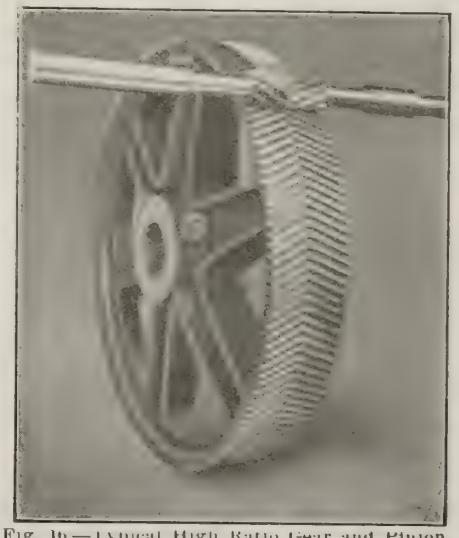

Fig. 16.—Typical High Ratio Gear and Pinion, the Latter with 8 Teeth.

teeth, for small pinions. Pinions with very few teeth are cut on the well-known system of enlarged addendum which is used for small wormwheels and bevel pinions. The teeth are cut to diametral pitch standards, measured circumferentially as with ordinary spur gearing.

Dimensions for Proposed Interchangeable System.

The dimensions proposed for an interchangeable system for these gears are as follows:

Tooth shape ....Involute.
Pressure angle ....20 deg.
Spiral angle ....23 deg.
Pitch diameter (20 teeth and over)= Number of teeth / D.P.

Blank diameter (20 teeth and over)= Number of teeth+1.6 / D.P.

Pitch diameter (under 20 teeth)= 0.95×Number of teeth+1 / D.P.

Blank diameter (under 20 teeth)= 0.95×Number of teeth+2.6 / D.P.

Addendum .... 0.8 / D.P.

Dedendum .... 1.0 / D.P.

Full depth .... 1.8 / D.P.

Working depth .... 1.6 / D.P.

Standard face width for gears with pinions of not less than 25 teeth .....6 times circular pitch

Face widths for high ratio gears with small pinions 6 to 12 times circular pitch

When a pinion of less than 20 teeth is used with a standard gear, the centre distance must be slightly increased to suit the enlargement of the pinion. If it is desired to keep the centre distance to the standard dimensions, the gear diameter may be reduced by the amount of the enlargement given to the pinion. For example:—If a pinion of 10 teeth, 5 D.P. is to mesh with a gear of 90 teeth at 10 in. centers.

Pitch diameter of pinion= $\frac{0.95\times10+1}{5}$ =2.1 in.

Enlargement over standard pinion= 0.1 in.

Pitch diameter of standard gear $= \frac{90}{5} = 18.0$ in.

Reduced pitch diameter of gear $= 18.0 - 0.1 = 17.9$ in.

Centre distance $= \frac{17.9 + 2.1}{2} = 10$ in.

Strictly speaking, there can be no enlargement or reduciton of the pitch diameter in a pinion or gear of given pitch and number of teeth. It is convenient to assume this enlargement and reduction, while using teeth with long and short addenda but standard depth.

In these gears the teeth need not have the same breaking strength as with spur gears because they have not to combat the heavy and indeterminate stresses which arise from inequalities of angular velocity. On the other hand it is necessary to provide against rapid wear. By using a finer pitch, each tooth has less individual wearing surface, but this is more than compensated for by the larger number of teeth in simultaneous contact than with gears of equal diameters but coarser pitch. In high ratio gears, using pinions of exceptionally small diameter, the pitch is finer than for ordinary ratios, but the face width is extended to give the proper wearing surface. The important factor in determining the proportions of the teeth is the relationship between pitch line velocity and the permissible specific tooth pressure; in other words, the total tooth pressure divided by the area of all the available simultaneous contact along the teeth. Theoretically, this contact has no area since it should consist of lines without breadth. Actually, an area exists, due to the elastic compression of the teeth in contact, in a similar way in which an area of contact exists between a car wheel and a rail. The area of contact is indeterminate, but the specific tooth pressure is proportional to the driving stress on the teeth.

Simple Rule for Finding Proper Dimensions.

In order to obtain a simple rule for finding the proper dimensions, the results of experience in the matter of safe working loads under given conditions have been reduced to a relationship between pitch line velocity and the shearing stress on the pitch line thickness of an imaginary straight tooth, assuming only one tooth in engagement at a time. The shearing stress is a measure of the specific tooth pressure, and the relationship referred to affords a convenient means of arriving at reliable dimensions. The curves, Fig. 7, give values of shearing stress K in pounds per square inch on pitch line section of an imaginary single tooth for corresponding pitch line velocities V in feet per minute. The values are entirely empirical, but they are based on the results of extended experience, and lead to dimensions which are safe and reliable. Different curves are given for different materials, and it is necessary to use that curve which corresponds to the lowest grade material of the combination. The dimensions of gears can be derived from the curves in the following manner:

h.p.=brake horsepower transmitted

N=revolutions per min.

D=pitch circle diameter, in.

p=circular pitch in inches (use nearest diametral pitch)

W=total width of face, in.

V=pitch line velocity, ft. per min.

P=total tooth pressure at pitch line, lb.

K=stress factor (from curve)

$$V = \frac{nDN}{12} \quad \ldots\ldots\ldots\ldots\ldots\ldots [1]$$

$$P = \frac{h.p. \times 33{,}000}{V} \quad \ldots\ldots\ldots\ldots\ldots\ldots [2]$$

$$P = \frac{pWK}{2} \quad \ldots\ldots\ldots\ldots\ldots\ldots [3]$$

$P = 3p^2K$ (in normal gears of moderate ratio, and face width equivalent to six times the circular pitch) $\ldots\ldots\ldots [4]$

$$p = \sqrt{\frac{P}{3K}} \quad \ldots\ldots\ldots\ldots\ldots\ldots [5]$$

For high ratio gears take $W = Rp$ (R = ratio to 1) up to maximum of $W = 10p$.

$$p = \sqrt{\frac{2.5P}{RK}} \quad \ldots\ldots\ldots\ldots\ldots\ldots [6]$$

Usually the values of h.p. and N are known. In many cases the diameters or centre distances are fixed, and there is no choice of dimensions. When the diameters are not fixed there are many solutions to the same problem and it becomes largely a matter of experience which to select in order to obtain the

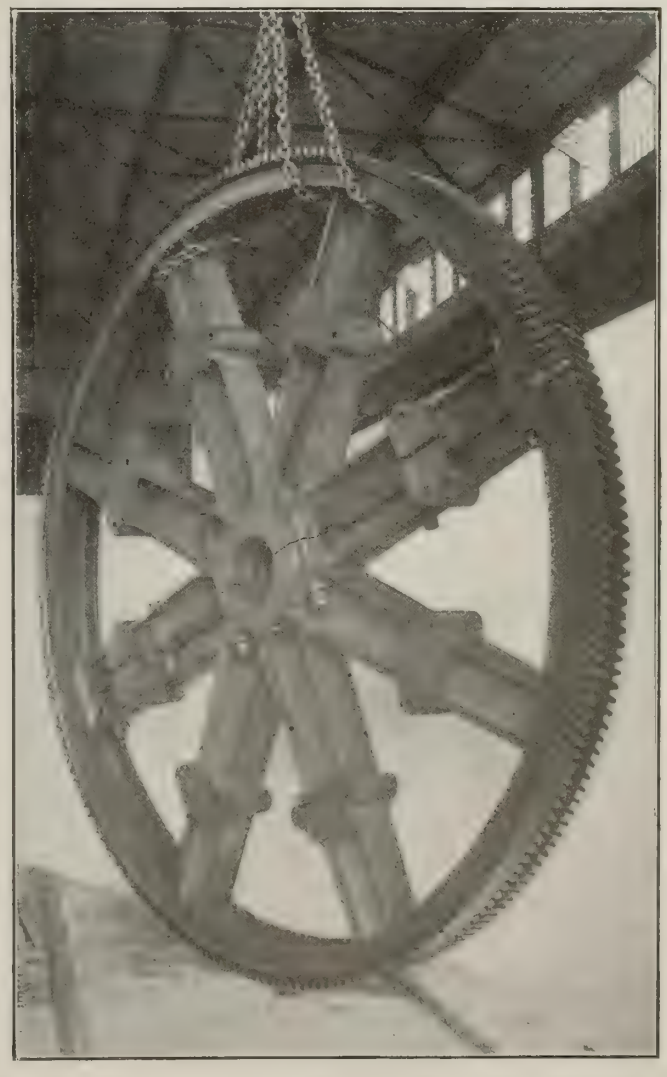

Fig. 15.—Semi-Steel Gear, 12 in. Face, 12 ft. Diameter for Mine Hoist.

most economical and satisfactory gears. In normal gears it is safe to aim at pitch line velocities between 1,000 and 2,000 ft. per min. with 1,500 ft. as a fair average. If the pinion is to be fixed to a motor shaft without external support, the diameter must be greater than when it can be supported on both sides. Cast-iron is preferable to cast-steel for gears of large diameters and moderate power, but the latter will be found more economical for high tooth pressures. Pinions are usually made from steel forgings of 0.40 to 0.50 per cent. carbon. Soft pinions should never be used for herringbone gears. Besides being bad engineering practice they are unnecessary, because steel pinions run without noise and last much longer.

Typical Instance.

The following is a typical instance of the range of choice in dimensions:—A pump which requires 150 h.p. at 50 r. p.m. is to be driven from a motor at 500 r.p.m. with shaft end 4½ in. diameter. It the shaft is unsupported, it is not desirable to use a pinion of less than 10 in. If the shaft is extended to a third bearing a 7½-in. pinion can be used. If the pinion is cut solid on its shaft and coupled to the motor, its diameter can be reduced to 5 in. The three arrangements work out as follows:

				Material for Gear	V	P	K	Diametral Pitch	Face Width
A	10 in.	and	100 in.	Cast-iron	1300	3800	500	2	9½
B	7½ in.	and	75 in.	Cast-iron	975	5100	530	2	12
C	7½ in.	and	75 in.	Cast-steel	975	5100	1060	2½	7½
D	5 in.	and	50 in.	Cost-steel	650	7600	1150	2½	12½

Any of the above gears will do the work satisfactorily. C is the most economical, but B or D would make the least noise. If a gear case is to be provided, then D will give the most economical combination.

The foregoing data can be used for finding the required dimensions of herringbone gears for all general applications. In most cases it is sufficient to calculate the tooth pressure from the average working load. When the maximum load is very far in excess of the average, it is usual to take a mean value between the two. Gears for electric mine hoists and single throw pumps fall within this category. Machine tools, when driven from variable-speed motors, are required to perform maximum duty at minimum speed only for short periods at long intervals. It is sufficient when getting out gears for a drive of this kind to reckon with the rated output of the motor at the mean between its maximum and minimum speed.

There are two special cases where the ordinary methods of calculation should not be used. Rolling-mill gears are subjected to stresses which are so far in excess of the average working load that it is necessary to consider carefully the strength of the teeth in regard to possible overloads. Extra high velocity gears, such as are used for steam turbines, require additional wearing surface and are characterized by extreme width of face combined with abnormally fine pitch. These are two extremes in gearing and their design is best left to those who have made a special study of them.

Summary of Gear Features.

Before describing some special applications of these gears to the needs of various industries and machines, it may be of service to summarize the salient features of the gears and the changes of viewpoint which these features have engendered. The smooth and continuous action is virtualy independent of the diameter or number of teeth in the pinion.

Extremely high ratios of reduction can be used without fear of uneven driving or undue wear and without fear for unwieldy gear diameters which would be disproportionate to the general design. High ratio gears of this type transmit power with practically no more loss than low ratio gears. They are far more efficient than belts, ropes, worm-gears or compound trains of spur gearing, while their adoption results in a wholesale reduction of countershafts and bearings which reduces the power consumption and running costs to a remarkable degree.

There are many instances where spur gears cannot be used because the vibration which they set up has a detrimental effect on the driven machine or its product. The inconvenience of a cumbersome system of belts or ropes has usually to be borne in such cases, but it is not too much to say that the requirements of almost all of them are fully satisfied by this type of herringbone gears.

The application of spur gears has been much restricted by the noise which they make when run at high velocities. The use of rawhide or other soft materials has only proved moderately successful for comparatively light work and is quite unsound for heavy gear practice. Herringbone gears in combination with durable steel pinions make less noise than soft pinions and spur gears when new, and while the former become quieter with use, the latter soon begin to rattle as they become worn. It should be noted that the use of soft pinions, while mitigating the nuisance of excessive noise, does not reduce vibration or unevenness of motion.

There is a limit to the pitch-line velocities at which spur gears can be operated and beyond which it is unsafe to use them. This limit is far below the minimum velocities which can be used in connection with steam turbines of economical design and high power. Accurate herringbone gears operate quite smoothly at velocities which are impossible for other types. This feature would appear to reserve for them a field of application which has great possibilities and is likely to cause some great changes in the standard practice of to-day.

Application to Steam Turbines.

There are many instances when the power of the turbine can be more conveniently applied in mechanical form than through electrical transmission. The advantages of high-power turbines have been discounted in many instances by the necessity for expensive electrical outfits with their attendant losses of generation, distribution and conversion.

Direct-connected steam turbines for marine propulsion have been only partially successful in a very limited field. The screw propeller, working in a dense medium, has an economic speed of rotation which is far below the best speed for a steam turbine of corresponding power. It is only when the power required is very great and the speed of the vessel unusually high that the direct-connected turbine can be applied, and even then the application does not do full justice to either turbine or propeller, while the first cost is much higher than it need be. The use of direct-coupled turbines is confined to ocean fliers and ships of war. Ordinary vessels of commerce, which are built in vastly greater numbers, cannot be adapted to turbine power in this form. Mr. Parsons attacked the problem of applying the turbine to an ordinary freight steamer of moderate power. To this end he purchased the S. S. Vespasian, a modern tramp with triple-expansion engines of about 1,000 h.p. and a speed of 11 knots with propeller running at 75 r.p.m. As a preliminary to the installation of geared turbines on this vessel, the original engines were overhauled and tuned up and a series of coal consumption trials made under regular sea-going conditions.

The engines were then removed and for them were substituted a pair of steam turbines connected to the propeller by the herringbone gears illustrated in Fig. 8. Each turbine develops about 500 h.p. at 1,500 r.p.m. The propeller runs at the original speed of 75 r.p.m. Each turbine is coupled to a herringbone pinion

with teeth cut solid on a shaft of soft-grade chrome nickel steel. The two pinions mesh with rolled-steel gear rings mounted on a cast-iron spider which is keyed to the propeller shaft. The whole gear system is enclosed in a case, and the teeth are kept lubricated by oil jets. The great width of the pinions in proportion to their diameter made it necessary to provide room for bearings between the right and left-hand teeth. The proportions of this remarkable gear unit are as follows:—Pinions, 20 teeth; gear, 398 teeth, 4 diametral pitch; teeth of involute form, 20 deg. pressure angle, 23 deg. spiral angle; over-all face width, 34 in. including 10 in. space for bearing; actual face width, 24 in.; ratio of reduction, 19.9 to 1.

Satisfactory Results Obtained.

This gear has now been running regular voyages for more than a year and has covered over 20,000 miles. The results have been interesting and satisfactory. The efficiency of the gear is fully 98 per cent., including the losses in the bearings on the gear case. The geared turbine shows a sustained all-round saving in fuel consumption of more than 25 per cent. over the original engines. The gear runs with remarkable smoothness and without noise or vibration. The wear on the teeth is negligible after 20,000 miles, being only 0.002 in. at the pitch lines of the pinions. Even this small wear is nearly all traceable to inadequate arrangements for freeing the oil from grit during the first runs.

Not by any means the least important gain is in the behavior of the vessel in rough water. There has been no racing of the propeller under circumstances where this disagreeable feature was painfully evident with the original installation. This is due to the high rate at which the turbine motors store up energy with change of speed, which makes it impossible for a large change to occur during the time when the propeller is partially uncovered. Such a record as this is so conclusive that the use of geared turbines for marine propulsion must shortly become general. Herringbone-geared turbines aggregating 3,600 h.p. have recently been fitted to the U.S.S.S. Neptune by the Westinghouse Machine Company. The performance of this vessel will be awaited with interest.

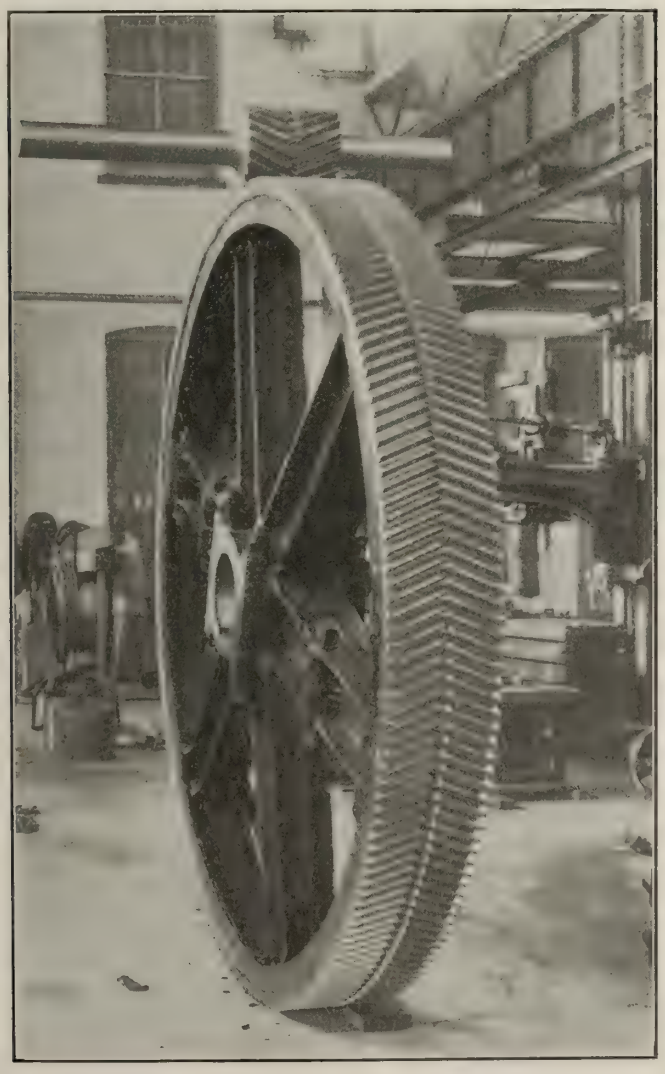

Fig. 17.—High Ratio Pump Gears. Gear 9 ft. Diameter.

Continuous Plate Mill Installation.

Mr. Parsons has made a successful introduction of herringbone gears in combination with a steam turbine for driving a continous plate mill. This is a proposition which few engineers would have considered seriously, yet it has proved a success from every point of view. The mill is of the three-high type with rolls 28 in. by 84 in. running at 70 r.p.m. The turbine is designed for mixed pressure, running at 2,000 r.p.m. with exhaust steam at 16 lb. absolute or live steam at 60 lb. absolute and giving 750 b.h.p. The turbine is coupled to the rolls through a double train of herringbone gears. The first train consists of a chrome nickel steel pinion, cut solid on its shaft and cast-steel gear. Pinion and gear have 25 and 131 teeth, 3½ diametral pitch by 24 in face. This train reduces from 2,000 to 375 r.p.m. and is coupled to the second train through a flexible coupling. The second train includes a high carbon steel pinion of 23 teeth and cast steel gear of 127 teeth, 2 in. circular pitch by 16 in. face. This train reduces from 375 to 70 r.p.m. The final gear is overhung on the end of a flywheel shaft 22 in. in diameter, which carries a flywheel of about 100 tons between two bearings and is coupled to the main pinion through a pair of wobblers. Both sets of gearing are enclosed in casings and are lubricated by oil jets from a pump provided for the purpose. This mill has been running without a hitch of any kind since September 15, 1910. The gears are noiseless, the installation shows remarkable efficiency, the rolls run with extreme smoothness and the pinions do not show appreciable wear.

Scope of Geared Turbine.

The success of the geared turbine for such an application as the one described makes it certain that similar arrangements can be used with advantage for driving textile and other mills where the conditions are less severe. The geared turbine is making rapid progress for driving direct-current generators, and several large sets are now running and in course of construction. Hitherto, it has been usual to couple the turbine to a high-speed alternator and to convert to continuous current through a motor generator or rotary converter. The geared turbine unit costs less money, takes up less space and has an overall efficiency at least 6 per cent. better than the A.C.—D.C. combination.

Geared turbines have another field of application for driving centrifugal pumps. Direct driven units of this kind have poor efficiency because a compromise has to be made between turbine and pump speed which is detrimental to both. The interposition of a set of herringbone gears allows both ends to be constructed for the highest economy, and since the

loss in the gears does not exceed 2 or 3 per cent. there is a large all-round gain in efficiency. This applies also to turbine-driven blowers and fans.

Geared Hydraulic Turbines.

The speed of hydraulic turbines is controlled by the available head of water supplied to them. The greater number of turbines are required to operate under low heads and must run at slow speed. Hydro-electric power has usually to be transmitted to a considerable distance and is produced in the form of alternating current of definite periodicity. The speed of the turbines may be as low as 50 r.p.m. or even less. A large direct-coupled alternator for this speed is an expensive proposition.

Herringbone gears can be used to speed up from the slow-running turbines to generators of normal design, speed and efficiency. The smooth action of these gears is unimpaired when the wheel drives the pinion, and high ratios of speed increase can be obtained from them without noise and with less loss than direct coupled units will give. A typical installation of this kind is outlined in Fig. 9. This arrangement shows two slow-speed vertical turbines driving one generator. A herringbone gear is mounted on each turbine shaft and both gears mesh with a pinion which is coupled to the generator.

Rolling Mills and Rod Mills.

There are two advantages in the use of accurate herringbone gears for this class of work. The absence of shock in transmission renders breakages much less frequent than with cut spur or moulded helical gears. The even transmission and entire elimination of vibration allows the finishing rolls to be gear driven for the finest work without showing gear marks on the finished product. Herringbone-geared mills run with very little noise. This may be of less consequence in rolling mills than in most other applications, but it is an improvement. Rod mills, with their quantities of high-speed gearing, can be completely transformed by using herringbone gears and mill pinions.

Machine Tools.

The field for accurate herringbone gears in connection with machine tool driving is too extended to be considered in detail. For individual motor drives this gear gives a positive transmission which is free from vibration and less noisy than-so-called silent chains or rawhide pinions, while there is no trouble from slipping belts or slack chains. But the real advantage of these gears lies in the better finish that can be obtained when they are used for the entire main transmission, and in the higher output combined with reduced maintenance which they give to heavy machine tools. Chatter is eliminated. Even the speeding up to the wheels of grinding machines has been successfully accomplished. Reversing gears for heavy planers are a revelation to those familiar only with the ordinary spur drive. Illustrations of machine tool drives are shown in Figs. 10 and 11.

Pump Driving.

Electrically-driven plunger pumps have not enjoyed the popularity that might be expected, due to the noise and vibration caused by the gearing between motor and pump shaft. These objections are obviated by accurately cut herringbone gears, which not only give silent and vibrationless transmission but admit the use of high ratio single reductions with compact dimensions. The single reduction drive has a much higher efficiency than the ordinary double frame, quite apart from the lower gear losses, because at least one countershaft can be dispensed with. Examples of such drives are shown in Figs. 12 and 13. Similar drives are successful for air compressors and vacuum pumps which present similar difficulties to those met with in plunger pumps.

Application To Mining.

One of the features in the recent electrifications of the Eckstein group of mines on the South African Rand is a train of herringbone gears between motor and drum in the main hoists. These hoists are driven by reversing asynchronous motors; the geared countershafts being connected to the drums by drag links from the original crank pins that were used when the hoists were run by steam power. The arrangement is shown in diagram in Fig. 14. Fig. 15 shows a large gear made for mining work.

In installations of this type there are no slipping clutches, and the strains on the gears are very severe, some of them having to transmit 3,000 to 4,000 h.p. at pitch line velocities ranging from 2,000 to 3,500 ft. per min.. The large coal mines in Northumberland, Yorkshire and South Wales are rapidly adopting high tension three phase current for the distribution of power below ground. Some very large main and tail, and endless, haulages are used in these, and herringbone gears have become a standard for this class of work. The hoists range from 30 h.p. up to 1,000 h.p., and invariably use a high reduction with ratios which are sometimes as great as 15 to 1. Simplification of design and saving of space is obtained in this way, since ordinary spurs require a double train. The gain in efficiency and absence of noise are remarkable, while the first cost of the whole outfit is often less than when cheaper gears are used. The elimination of all vibration prevents crystallization of the shafts and disintegration of the insulating material in the motors. These gears offer the same advantages for endless haulages. A higher speed motor can be used when they are adopted, while no more than two trains of gears are required.

An application of especial interest is for driving tipplers. These gears for this purpose have replaced worm gears because they stand up to the heavy strains without excessive wear. The available space for the gears is always limited in such cases. The gears have a ratio of 7 to 1 with a seven toothed pinion and a gear of only 20 in. diameter. Some typical high ratio gears are shown in Figs. 16 and 17.

Elevators.

There are very few high buildings in Europe and the elevators there run at comparatively low speeds. As a consequence, worm gears predominate for this class of work. The Wuest type of gear was brought out with a view to overcoming the losses inseparable from worm gears with high ratios. The needs of American sky-scrapers have caused the development of elevators in this country to run on different lines, so that the popular type of to-day has the rope sheave direct connected to the motor. Needless to say the motor runs at exceedingly slow speed, usually not more than 50 to 60 r.p.m. as a maximum. Such a motor is expensive and inefficient. The system of control is wasteful to a degree. Field regulation is out of the question, and the speed control is obtained by shunting the main current through a resistance so as to reduce the volts across the armature of the motor. The survival of so uneconomical a type of machine is due to there having been no satisfactory gear system which would fit the peculiar conditions. A number of elevators are now being equipped with herringbone gears. The motor is geared to the sheave through a single train with a ratio of about 10 to 1. The maximum motor speed is about 500 r.p.m. and the speed control is nearly all obtained by simple field regulation. The following advantages are claimed:—The power consumption is not more than 60 per cent. of what is required for direct connected motors, the electrical switchgear is far more simple, has less to do and is not so liable to get out of order; the motor can be repaired without interfering with the car or its suspension.

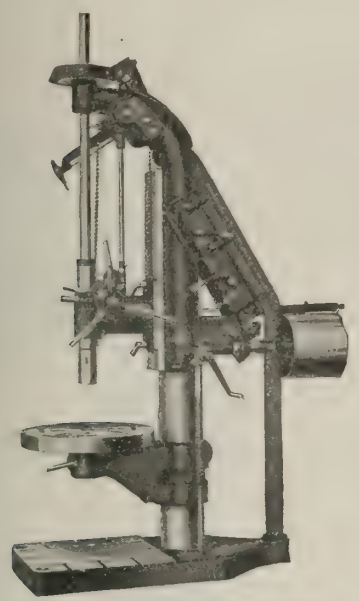
The Falk Company, Milwaukee, Wis., has acquired the sole rights for the United States under the Wuest patents and during the past year have been constructing some of the most powerful gear-cutting machinery in existence with a view to securing the required degree of accuracy in the production of gears of this type.

DEVELOPMENTS IN MACHINERY

A Record of New and Improved Machinery Tending Towards Higher Quality and Economical Production in the Machine Shop, Blacksmith Shop or Planing Mill.

ALL GEARED SLIDING HEAD DRILL

THE powerful 26-inch all geared, sliding head drill shown in the halftone has lately been put on the market by the Barnes Drill Co., Rockford, Ill.



All Geared Sliding Head Drill.

In its general lines it follows after the design of other all geared drills built by this firm, but has in addition a sliding head. The drill is belt driven from a line shaft, or may be had complete with motor drive if desired. There are eight geared speeds and eight geared feeds, the latter ranging from .005 inch to .086 inch. The head and spindle are counterbalanced, the weight being suspended by a roller bearing sheave. The spindle is extra large—1 15-16 inches diameter—and is double splined. The head is gibbed to the column face, insuring perfect alignment, and is held at any point of its 23-inch travel by two clamp screws. It is raised or lowered quickly and easily by means of a crank pinion engaging with a rack. This feature is advantageous for boring bar and deep hole work, for which the machine is well adapted. It will bore a hole 8 inches in diameter or larger, and is guaranteed to drive a 2-inch high speed twist drill in cast iron at a feed of .041 inch per revolution of spindle, without using the back gears. The spindle is bored to fit a No. 4 Morse taper shank, or may be had to fit No. 5, if specially ordered.

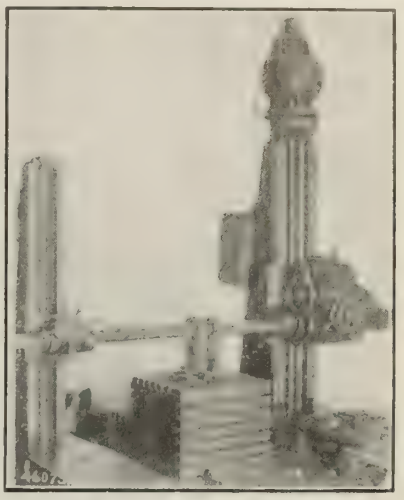
The fast and loose pulleys are 12x5 inches, and are run 325 r.p.m. The floor space occupied is 22x49 inches, exclusive of the pulleys which project 10 inches. The net weight of the machine is 1,750 pounds, or 1,950 pounds crated for domestic shipment. Further dimensions are given in the following table:—

	Inches
Height of Drill	92½
Distance from turned column to center of table	13¼
Distance from face of column to center of table	12
Diameter of column	7½
Diameter of table	23
Vertical travel of table	20
Vertical travel of spindle	14
Travel of sliding head	23
Greatest distance from spindle to base	54
Minimum distance from spindle to base	18½
Greatest distance from spindle to table	40

GRINDER WITH WHEEL GUARDS.

THE accompanying cut illustrates the No. 5 grinder fitted with wheel guards, recently brought out by the J. G. Blount Co., Everett, Mass. This is one of a line of seven grinders built by the firm designed to take wheels from 8 to 30 inches in diameter. The No. 5 grinder takes 16 inch wheels, 2½ inches thick, the arbor being 1¼ inches diameter. The bearings are babbitted and line reamed, the spindle being ground to fit. Bearings are made self-oiling by means of wool-felt wick. The pulleys are put on under pressure, thus doing away with the necessity for set screws which frequently work loose and cause more or less trouble. The wheel guards are made in seven sizes and can be fitted to any of the Blount grinders. They constitute a feature highly to be commended, and may be the means of preventing serious accidents. They are attached to the back of the head and are adjustable to allow for wear of the wheels.

Grinder with Wheel Guards.



Vertical Motor Drive for Boring Machine.

The J. G. Blount Co. have recently got out a new catalogue of their grinding and polishing machinery, which gives full particulars of the machine here illustrated.

VERTICAL MOTOR DRIVE FOR BORING MACHINE.

PROGRESSIVE manufacturers are always cognisant of the importance of selecting an efficient drive for their machine tools. They readily perceive that the most direct or shortest distance between the source of power and the work, means not only more work with less power, but also reduced operating costs by eliminating many superfluous lines of shafting with belts to each machine, dripping oil, and the difficulty of speed changing. By the use of individual electric drive, the machines may be located in the most convenient places for the work they are to perform, rather

than in a row and driven from one line shaft. The economy and flexibility of individual motor drive cannot be too greatly emphasized, since this form of furnishing power has been largely responsible for the increased output of many varied industries.

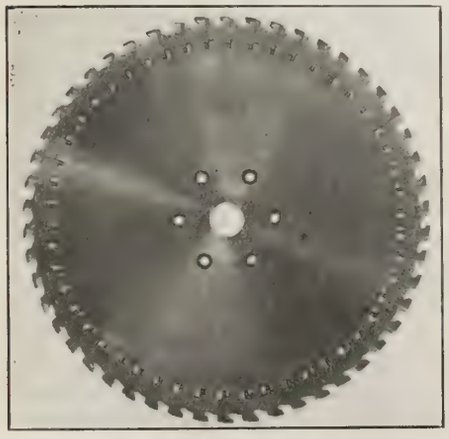
In the building of machine tools, another important factor, usually given careful consideration, is the saving of floor space. This opens a new field for electric motor by mounting directly on the top of the machine to be driven. The electric motor is ideal for this purpose and has found especial favor with machine tool manufacturers due to its adaptability to direct mounting. It matters little whether the motor be attached to a movable or stationary part, for the drive will be equally efficient.

High mounting also affords the operator plenty of space and at the same time keeps the motor remarkably free from dirt, chips and loose particles which often fall into it.

A particularly interesting and somewhat unique example of the manifold advantages of individual motor drive, applied to machine tools, is shown by the accompanying illustration. This horizontal boring machine is built by the Rochester Machine Tool Co., Rochester, N.Y. The motor is a 5 h.p., vertical type R, made by the Westinghouse Electric & Manufacturing Co., East Pittsburg, Pa. The method of mounting the motor on the top of the column, as illustrated has proved particularly satisfactory in securing maximum efficiency, and it is surprising to us that motors of such small capacity should prove ample for the heavy work accomplished.

DUPLEX INSERTED TOOTH SAW BLADE.

THE accompanying photograph shows the recently perfected Hunter Duplex Inserted Tooth Saw Blade, manufactured by the Hunter Saw & Machine Co., Pittsburg, Pa. This blade, designed for cutting forgings, steel castings, bars, rails, frogs, switches, etc., is manufactured in sizes ranging from 6 to 84 inches diameter, and of thickness most practical for the class of material to be handled. The blade body is made of the best grade of vanadium alloy tool steel, while the teeth, made of the finest grade of high speed steel obtainable for metal cutting, are properly hardened and treated. The teeth are secured by interchangeable tool steel wedges, lowered to brass adjusting screw. Roughing or round tooth is adjusted higher than finishing or flat tooth, so that a parting cut can be made, taking the remaining portion of material with the flat or finishing tooth.



Duplex Inserted Tooth Saw Blade.

Recent tests have been made with a 30-inch blade, wherein 1,275 cuts were made in 65½ hours on .61 carbon steel splice bars at a lateral feed of nine-sixteenths (9-16) inches per minute, bars being piled four high. A 40-inch blade, cutting .45 carbon round bars of hammered machinery steel, showed the following results, which are claimed to be a record for inserted tooth saw blade.

12	in.	diameter—	5 minutes.
9	"	"	—3 minutes.
6½	"	"	—1 minute 30 secs.
6	"	"	—1 minute, 22 secs.
5	"	"	—1 minute.
3½	"	"	—25 seconds.

REMINGTON GRINDING ATTACHMENTS.

FIG. 1 shows an external grinding attachment for bench lathes designed with a view to securing the greatest degree of rigidity for grinding with half-inch face and 4-inch. diameter wheels. The grinding head may be removed and head for internal grinding substituted. The spindle for internal grinding is capable of speeds up to 30,000 r.p.m. The circular swivel base is graduated in degrees, to permit of tapers being ground. The lever movement is stantly carried away from, or returned to the work, greatly facilitating the fitting of gauges and placing of work. The emery wheel is covered, and is provided with an adjustable tube, to direct the flow of water, in wet grinding.

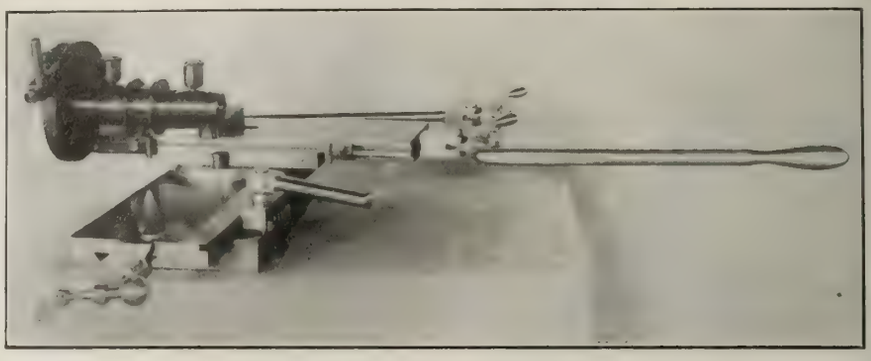


Fig. 1.—Remington Grinding Attachment.

Fig. 2 shows an external grinding attachment for bench lathe for grinding irregular forms without the necessity of resetting for different angles. It is particularly adapted for grinding hardened steel paper cutters. In the illustration is shown a paper cutter which has been ground on the plane, concave, and bevel, in one setting. Fine adjustments have been provided throughout, both for setting the wheel and to compensate for wear. The circular swivel base is graduated in degrees for setting wheel for varieties of work.

Both of the foregoing attachments are recent developments of the Remington Tool & Machine Co., of Boston, and are designed to be used with the manufacturer's bench lathe which they build.

Fig. 2.—Remington Grinding Attachment.

THE WIGGLESWORTH BORING MACHINE.

THE Western Machine Tool Works of Holland, Mich., have recently placed on the market the Wigglesworth boring machine, especially adapted for the heaviest kind of boring, drilling and tapping. The machine is capable of handling 4-inch drills in steel, and of pulling an 8-inch pipe tap in cast iron.

In Figs. 1 and 2 may be seen the general features of this machine. As will be noted, the spindle remains in a fixed position, the head mechanism being fed down automatically on the column. The machine is equipped with nine changes of geared positive and independent feeds, ranging from 0.006 to 0.042 inch per revolution of the spindle, and three positive geared leads for tapping, 8, 11½ and 14 threads per inch. These tapping leads are independent of the 9 feed

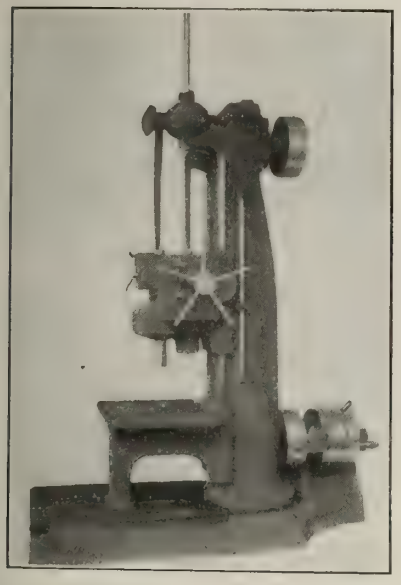

Fig. 2.—Wigglesworth Boring Machine.

changes. Any desired tapping leads may be obtained by means of other change gears, furnished as an extra.

As will be noted, a belted connection is made on this machine, between the countershaft on the base and the quick change speed gear box on the top of the column. The countershaft carries tight and loose pulley, 16x5 inches, and runs at a constant speed of 400 r.p.m. In the speed change gear box, eight different spindle speeds are obtained, which are doubled in the head by means of back gears, making 16 spindle speeds in all, ranging from 25 to 400 r.p.m. From the gear box, the power is transmitted to the head proper through a set of three bevel gears and a friction clutch, which form the reverse mechanism for tapping. The long lever for operating this friction clutch is located conveniently on the left hand side of the head as shown in Fig. 1.

In the head, the spindle is driven by a large gear located in a fixed position, at the lower end of the spindle close down to the work. This arrangement reduces the torsional strains on the spindle and stiffens it, thus reducing the chatter usually present when taking heavy cuts.

The automatic down feed to the head on the column is driven from a spiral gear located near the upper end of the spindle. From here it goes through the quick change feed gears to a spur gear which meshes with a rack cut in the face of the column. It will be noted that this arrangement necessitates the feed operating strictly in conjunction with the spindle movements, and that the spindle does not move down through the head, but that the whole head moves down carrying the spindle with it.

The design of this machine is of the most improved type, and is extremely rugged and rigid throughout, although as compact as possible. The construction of the column is of especial interest. It will be noted that the cross sectional area of the column increases from the top downwards. This is because, as the head is raised, the bending stresses at the base of the column are increased, necessitating a greater cross sectional area at the base of the column than higher up.

In the old-style turned columns not only has the strength and rigidity been sacrificed by turning off the cast iron scale, but due to the equal cross sectional area along the entire length, the lower part of the column is too weak and the upper part carries an excess of metal which is useless as far as lending strength or stiffness is concerned. This has been proved by a number of tests on the two types of columns under exactly the same working conditions. The bending in the new type of column was less than 1-3 of that in the turned type.

As stated above, the machine is especially adopted for tapping. By means of the long lever on the left of the machine, the tap may be fed down with a geared positive lead, reversed and positively fed out. This obviates the old trouble of the tap dragging when being backed out and thus roughing up the threads. The result is a fine, clear tapping job. It should be noted that the spindle receives its motion from a low hung drive, i.e., the motion is imparted to the spindle by a gear placed close down on its lower end near the work. As the head moves down the driving gear remains at a fixed distance from the tool because the head itself moves down on the column carrying the spindle with it.

On the under side of the table, below the centre of spindle, a hub is bored out and heavily ribbed on the outer edges. Thus, when a boring operation, like an open end cylinder job, is to be performed, all that is necessary is to drill and bore out a hole through the table into this hub and insert a bushing. The boring bar can be run through and steadied in this bearing. In this manner a support to both ends of the boring bar is obtained, the great advantage of which can be readily seen. The cutter will feed down through the work with an accuracy of alignment and freedom from spring and chatter that is obtainable in no other way.

The lubrication of this machine is automatic throughout. All gears in the head and quick change gear box are steel or bronze and dip in a bath of oil, the head alone holding seven gallons of lubricant. The bearings are made self-oiling by laying a wick in a slot milled out of the bearing, the ends of the wick dipping

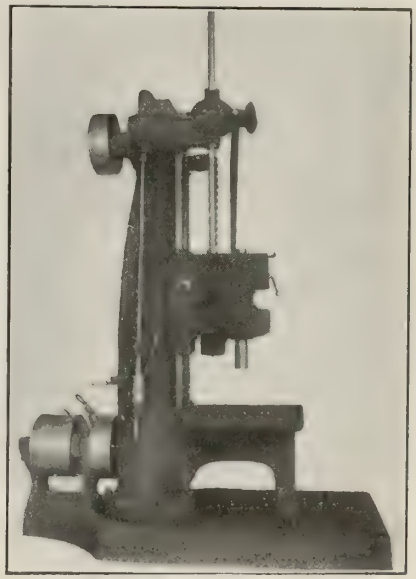

Fig. 1.—Wigglesworth Boring Machine.

into a reservoir of oil. The same is true of the loose pulley on the countershaft, where the ends of the wick dip into a reservoir cored out of the hub. These reservoirs hold enough oil to last for several months with the machine in constant service.

Regarding the general specifications of this machine, there are regularly furnished three positive geared leads for tapping, 8, 11½ and 14 threads per inch. There are also 9 geared positive and independent feeds to the spindle ranging ing from 0.006 to 0.042 inch per revolution of the spindle; the automatic down feed to the head on the column is 40 inches, the distance from the face of the centre of the spindle is 14½ inches, the diameter of the column front to back is 18 inches, and the size of base 40x90 inches. The machine weighs about 8,500 pounds.

When motor drive is desired, all that is necessary is to place a motor on the

base back of the column, in place of the countershaft. The Wigglesworth boring machine may be seen in operation by a visit to one of the demonstration shops of Hill, Clarke & Co., Inc., of Boston and Chicago, and their branch offices at New York, Philadelphia, Cleveland, Milwaukee and Rochester.

UNIVERSAL SPIRAL GEAR HOBBER.

THE Adams Co., Dubuque, Iowa, has added to their line of Gear Hobbing Machines a No. 4, adapted to cut spur, spiral, worm wheels and worms, up to 24 inches diameter, 3 pitch in cast iron, and 3½ pitch in steel. This machine is capable of such a wide range of feeds and table speeds as to make it universal. It can be arranged, and change gears furnished to cut a single thread worm or screw of fine pitch, and from that, on up through all pitches and number of teeth of worm, spiral and spur gears, including all prime numbers up to a thousand or more. The vertical feeds of the cutter head range from .002 to .500 inch for one revolution of the table. The table may be geared to make one revolution to two revolutions of the cutter, or it may be geared to make one revolution to a thousand or more revolutions of the cutter. This range of feeds and table speeds is, of course, unnecessary for ordinary spur, spiral and worm gearing, yet no additional complication has been introduced to obtain it. The design of the drive of the table and feeds is such that the compounding of a comparatively small number of moderate size gears enables this range to be had.

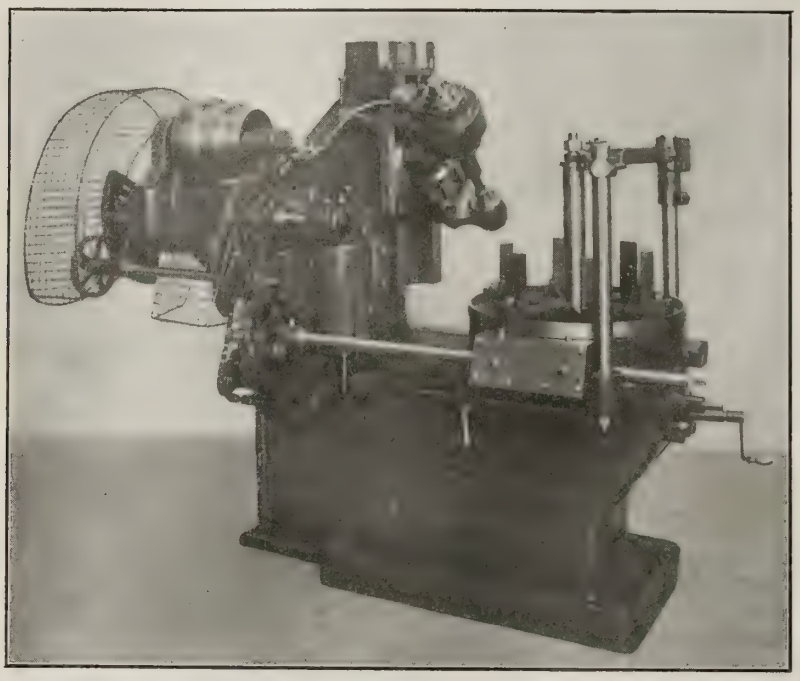

Fig. 1.—Universal Spiral Gear Hobber.

The machine is especially designed for gear and worm hobbing, but the slow table travel obtainable, relative to the cutter speed, enables the machine to be used also as a continuous or circular milling machine. A special spindle and bracket such as shown in Fig. 4 may be had for this purpose. Unusual weight and width of saddle and swivel is provided to increase the rigidity to the greatest extent. The cutter spindle is large and has a hole through which the arbor proper passes and is driven by a long key and feather. Adjusting nuts on the arbor at each end of the spindle provides for an end adjustment of the hob to facilitate setting one tooth central and to shift to fresh cutting position. The spindle is driven by a steel spur gear and pinion, and both spindle and pinion shaft run in adjustable bronze bearings on each side of the gears, thus equalizing the strain.

Fig. 3.—Universal Spiral Gear Hobber.

There is but one pair of bevel gears in the spindle drive train, two pairs less

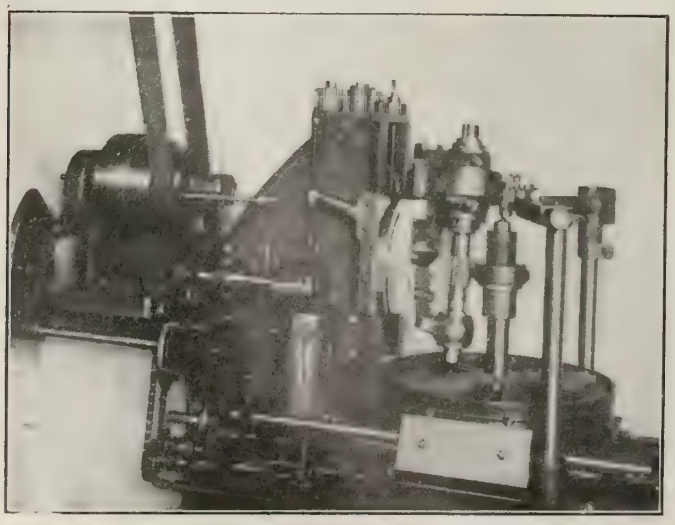

Fig. 2.—Universal Spiral Gear Hobber.

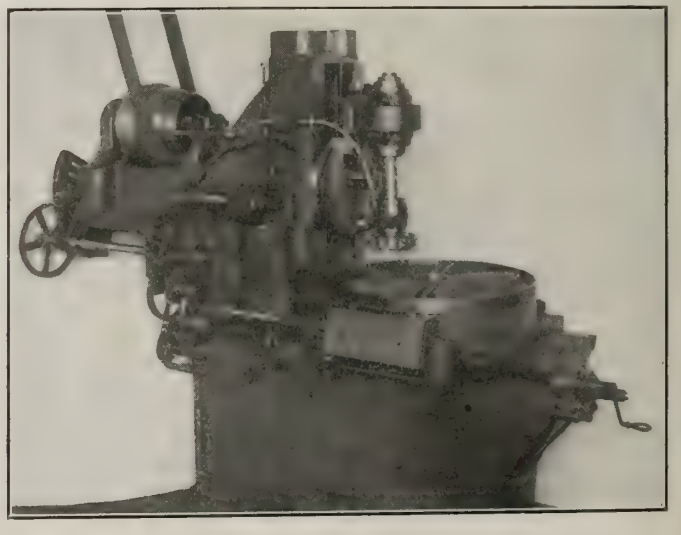

Fig. 4.—Universal Spiral Gear Hobber.

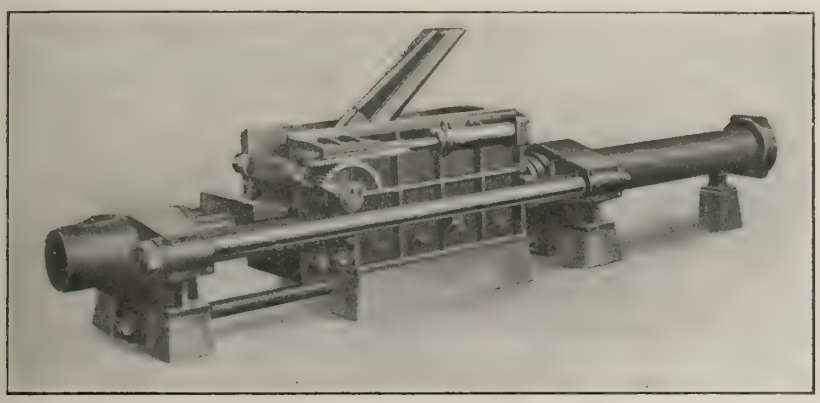
than usually found in swivel head construction. There is no long spliced shaft and sliding key used in the drive.

A reducing gear of large diameter is interposed between the cone pulley shaft and a universal joint shaft which communicates power to the spindle. This is the same drive which has been found so satisfactory in the No. 3 machine. The universal joints, of special design and very strong, are provided with large wearing surfaces of steel on bronze. They have ready means to compensate for wear, and are equipped with felt oil retaining pads to facilitate lubrication. The cutter head has a vertical power feed ranging from two thousandths to one-half inch to each revolution of the table. An automatic stop and a rapid power return is provided. The table saddle has a power inward feed ranging from one quarter thousandth to three-eighths inch to each revolution of table, and an automatic depth stop is provided for worm wheel hobbing.

A regular set of change gears, 120 in number, will give all feeds, and will cut all gears to 200 and many composite numbers above. Special gears can be furnished to cut other numbers including all prime numbers. The countershaft furnished is provided with three clutch pulleys; being a hobbing speed in both directions and a slow speed for driving milling cutters such as shown in Fig. 4.

The lubricating pump is arranged to run in the right direction when the motion of spindle is reversed. The table is driven by a steel worm engaging a bronze ring worm wheel. This worm wheel is 20 inches diameter in the 24-inch machine. Provision is made for easily taking up wear either in the mesh or end motion of the worm. The table is of heavy rib or spoke and rim construction, but the top between the ribs, instead of being level, is depressed in a cone shape with a hole in the centre. This conducts all cuttings and lubricant into a pan in the base of the machine. The lubricant drains out of the pan into a tank below. This pan may be easily removed through the door and contents dumped, handles being provided for the purpose. The weight of the machine complete is about 3,900 lbs.

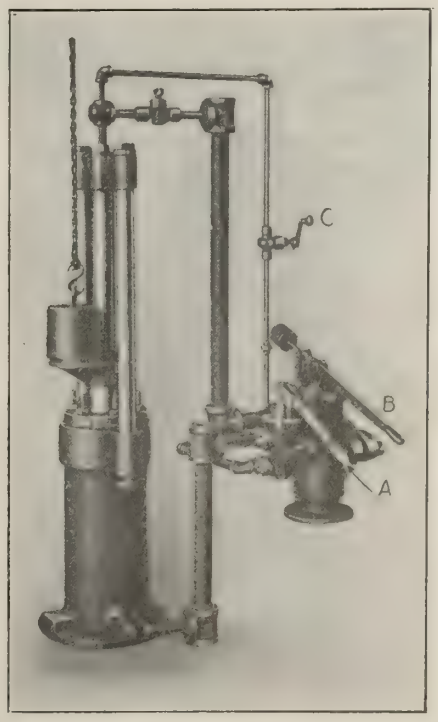


Sheet Steel Scrap Baling Press.—200 Tons.

BALING SCRAP SHEET METAL BY HYDRAULIC POWER.

SCRAP from sheet iron, such as is used in the manufacture of electric motors can be made worth something like $6.00 per ton more by compressing into bales, because of the labor saved in handling the latter; hence, delivery in baled form warrants the installation of baling apparatus in any plant where there is much of this material.

The illustrations show a type of press and its operating system recently designed for this purpose by The Watson-Stillman Co., of New York, and installed by the General Electric Co. This particular type of press takes scrap from the floor, compresses the material, pushes the bale out and drops it beneath the floor on to a runway. From the end of this runway the bale can be dumped on to an elevator from which, in turn, it can be put on to another runway and delivered to a freight car. With suitable pump and accumulator service, this press forms from 15 to 25 bales (about 2 to 3 tons of material) per hour, the output depending upon the skill of the operator.



Safety Governor.

The press, approximately 23 feet long, 4½ feet wide, 4¼ feet deep, is set in a pit about 6 feet deep and 30 feet long and rests on pedestals to give room for repairs if necessary. The working parts consist of (1)—a scrap or pressing box, the top of which is flush with the operating floor line, and which has hydraulically operated cover, and, (2)—two opposed hydraulic cylinders. One of these closes the box and the other compresses the bale and pushes it out. The pressing box is 60 inches long by 20 inches wide by 30 inches deep, which depth is reduced to 10 inches by the closing of the cover. The larger of the cylinders (at the left in the picture) closes the front end of the press, at the same time acting as a lock to the cover when it is closed, and is controlled by the same valve as the main or compressing cylinder (at the right). The compressing cylinder is double acting.

Pressure is supplied to the closing cylinder and the working end of the compressing cylinder from a variable pressure belted hydraulic pump. This pump has large pistons which deliver up to 1,500 lbs. per square inch, and are automatically cut out of action by the smaller ones as the pressure goes above the figure named, and continue in operation until a maximum of 4,900 lbs. per sq. in. is reached. At the instant of highest compression, the pump has a maximum duty of about 40 h.p. Pressure for the cover-closing cylinder and for pulling back the ram of the compression cylinder is furnished at 1,500 lbs. per sq. in. from an accumulator, served by a separate small pump, and loaded with about 15 tons of pig iron.

Service Operation.

In service, the action is as follows:—About 250 lbs. of material are shovelled into the box and the valve A is moved This admits accumulator pressure to the cover cylinder, forces its ram outward and closes the cover through the rack and pinion. One movement of the valve B then puts pump service simultaneously upon both closing and compressing cylinders. This first sends the ram of the closing cylinder forward until at the limit of travel it locks the box cover into closed position; then as pump pressure in the outer end of the compressing

cylinder goes above and overcomes the accumulator pressure in the pull-back end of the cylinder, the compressing ram moves forward until the pump pressure reaches the maximum of 4,900 lbs. per square inch. The parts are so proportioned that this gives a total finishing pressure of 200 tons upon the bale, which reduces its dimensions to about 20 inches by 10 inches by 10 inches, and makes it so compact that no straps are required.

A second movement of the valve B releases the forward pressure in the closing cylinder, thus permitting the compressing cylinder ram to continue pushing the bales to the left and out of the press and at the same time returning the closing cylinder ram to initial position. A third and final movement of the valve B then releases the forward pressure on the compressing cylinder ram, the bale drops down into the delivery chute, and the accumulator pressure which has been constantly acting on the return end of the compressing cylinder ram brings this latter back to initial position.

Governor Protection.

Protection from harmful overpressure is provided in the safety governor (shown at the left in the second illustration) which shuts off the pump at the limiting pressure. This governor has two cylinders with pistons of different diameters, the larger at the bottom and in direct contact with the accumulator pressure, 1,500 lbs. per sq. in. The smaller is direct-connected to the discharge pipe of the large automatic variable pump. The accumulator pressure being constant on the larger piston, the shelf supporting the weight is normally in its highest position. With the weight here, the pump discharges through the large operating valve either to the press cylinders, or back to the reservoir. When the valve is set for admission to the press cylinders, pressure in the top part of the governor is gradually increased. As the bale compresses, the low pressure plungers are first thrown out automatically, after which the two high pressure pistons continue the work until the maximum pressure of 4,900 lbs. per sq. in. is reached. When this happens, the 4,900 lbs. pressure also acting in the top or small cylinder of the governor, overcomes the pressure in the other end, forces the piston with the shelf downward, releases the weight and causes the high pressure plungers of the pumps to be by-passed. By opening the small valve C, shown in the vertical pipe line, the pump is started again.

Where desirable to deliver the finished bale on to the operating floor, a three-cylinder construction is necessary, the extra cylinder being placed vertically under the bale, and the upper end forming the bottom of the baling box. The dimensions and operating plan of such a system can, of course, be varied to comply with any service conditions.

BLOWERS FOR OIL FURNACES.

THE blowers for oil furnaces in connection with the N.T.R. shops, Transcona, Winnipeg, were specially designed by the Canadian Buffalo Forge Co., Montreal. The blower installation in itself is of considerable interest.

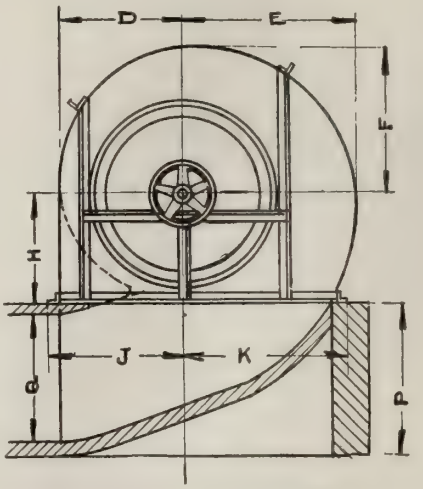


Fig. 1.—Blowers for Oil Furnaces.

The fan for the boiler shop consists of a No. 12 steel pressure blower, with down discharge, connecting to the underground distributing pipe, which is placed 13 inches below the floor level. From the outlet of the blower, a large sweep elbow is thus allowed. The larger blast pipe, increasing from 18 to 24 inches diameter, not only provides for future extension in case it is found necessary but also regularly reduces the friction which is inevitably incurred wherever it is attempted to force air through piping at a high velocity. This blower is designed to deliver 10,000 cubic feet of air per minute, at a pressure of 16 oz. when running at 1,750 r.p.m., and is direct connected with flexible coupling to a 75 h.p. Allis-Chalmers-Bullock Co. motor. A special feature of the whole installation is the fact that the blowers are, for all the large groups, direct connected to motors, thus eliminating belts and the constant repairs necessary where the alternative method of countershaft and belting is employed.

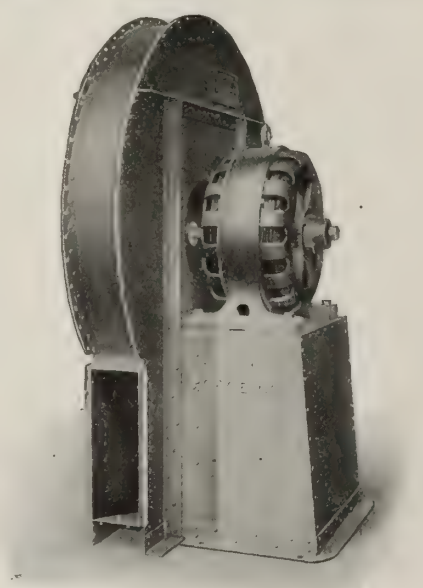

Fig. 2.—Blowers for Oil Furnaces.

In the blacksmiths' shop, the air blast is divided into two separate systems, one being supplied by another No. 12 steel pressure blower of exactly the same design as the one described above for use in the boiler shop. The other outfit consists of a Canadian Buffalo Forge Co. special steel plate blower, to deliver 6,400 cubic feet of air per minute at 14 oz. pressure and 1,750 r.p.m. This is direct connected to a 50 h.p. Allis-Chalmers-Bullock Co. motor.

In the spring shop there is a similar blower, slightly smaller in size, to deliver 4,800 cubic feet of air per minute, at 14 oz. pressure and 1,750 r.p.m., direct connected to a 40 h.p. motor. In the frog shop there is one No. 5 Buffalo special steel plate blower to deliver 2,700 cubic feet of air per minute at 1,750 r.p.m., direct connected to a 25 h.p. motor.

The steel plate blowers on this installation are specially interesting, due to the fact that they are built of the three-quarter housing type, Fig. 1, which means that the lower quarter of the fan is below ground. Further, the fans are of the bottom horizontal discharge construction, so that the outlet is also below the ground, and directly in line with the blast pipe, eliminating at least two elbows and giving a free positive flow of air direct from the paddles of the fan blast wheel.

A further special feature is the construction of blowers of this type for delivery of air at such a high pressure as 14 oz., and with a speed so low as 1,750 r.p.m. The standard blower, supplying 2,700 cubic feet of air per minute at 14 oz. pressure, would need to operate at a speed of approximately 4,000 r.p.m. The desired results are secured by the use of a special narrow housing, Fig. 2, with blast wheel of large diameter, and having a larger number of blades than in the ordinary design.

In connection with the furnaces in the coppersmith shop and for coal burning forges, there are three other blowers of the standard steel pressure type operating at 6 oz. pressure.

Vol. VIII. MARCH, 1912 No. 3

MUSEUMS OF SAFETY.

NOT the least important feature of the upward and onward progress of the Arts and Manufactures is that which has found concrete expression in the establishment of Museums of Safety in many leading commercial cities throughout the world. The present attainment has been a work of 25 years practical application, yet the efforts put forth have not only justified themselves but warrant the belief that an era of much more rapid development and increased usefulness lies ahead in this important field.

To enable our readers to get a thorough grasp of what is embraced by the term, "Museum of Safety," we reproduce in part a memo from the constitution of the American Museum of Safety, Incorp.:—"The objects of the corporation hereby created are to study and promote means and methods of safety and sanitation; the application thereof to any and all public or private occupations whatsoever; the advancement of knowledge of kindred subjects, and to that end to establish and maintain a museum, library and laboratories, with their branches, wherein all matters, methods and means for improving the general condition of the people as to their safety and health may be studied, tested and promoted, with a view to lessening the number of casualties, avoiding the causes of physical suffering and of premature death, and to disseminate the results of such study, researches and test by lectures, exhibitions and publications."

From the foregoing, it will be at once seen that the ideal aimed at is intensely practical and humane, and, being so, cannot fail to interest and commend itself to everyone connected with our large and small industrial organizations. These Museums of Safety are absolutely non-commercial, therefore, no orders are taken, no exhibits are sold, and the management takes no part in the promotion of devices. In a majority of cases, the exhibits are not patented, hence, those desirous of availing themselves of the opportunity to produce a duplicate for service, may do so. Space for an exhibit, also spectator's admission are each free, and demonstration costs are borne by the Museum Management. No exhibit is accepted unless a safety feature is apparent, and has been passed upon by the Board of Approval.

The value of such institutions, the scope of which we have outlined in the briefest possible manner, is inestimable. Men from all departments of manufacturing industries are to be found visiting these Museums, investigating details of the various contrivances shown, discussing the possible application of one or other to their particular business, and making dimensioned sketches to enable an equipment to be made and placed in operation to husband and protect life to the fullest extent possible.

The extent and scope of Canada's development in almost every field of manufacture warrants we believe the establishment in each of our leading industrial centres of a "Museum of Safety," and we feel justified in expressing the opinion that those responsible for the direction and management of our many large industrial corporations will not be lacking with a ready response. No more effective contribution to "higher efficiency" and none so easily realizable is evident than that of employees inspired with confidence in the efforts put forth to safeguard their health and lives, and it goes without saying, that to no other scheme of business management, is there the same hearty and willing co-operation extended. The instinct of self preservation is more or less strong in every type of human being, and best feature of all, perhaps, is that it reaches out equally strong to a man's fellow.

THE STEEL RAIL CONTROVERSY.

THERE was recently inaugurated in New York City a much needed conference between representatives of railroads and steel mills with the object of arriving at an agreement as to what constitutes a safe rail and to consider the whole subject of improving the character and quality of rails generally. For the last fifteen or twenty years the mills have been called upon to supply rails having an ever increasing carbon-content and have delivered same, though not without protest. This demand commenced about the year 1890, and of course, had for its object the reduction of rail wear caused by increasing traffic. Gradually, the railroads specified higher and higher carbon, until the alarming number of fatal accidents due to broken rails has called a halt, and brought to a head the controversy between the users and the makers.

We feel sure the conference will be productive of much good. The roads have, perhaps, been too much inclined in the past to place economy before safety, and it seems clear that they must in future be prepared to use a somewhat softer and less brittle rail, but one of somewhat heavier section in order that it may have as long a life as its high-carbon predecessor. This is the remedy for the present state of affairs suggested by Mr. James A. Farrel, president of the U. S. Steel Corporation, when recently giving testimony before the Stanley investigating committee at Washington, and appears to us to be the only satisfactory solution of the difficulty.

MACHINE SHOP METHODS AND DEVICES

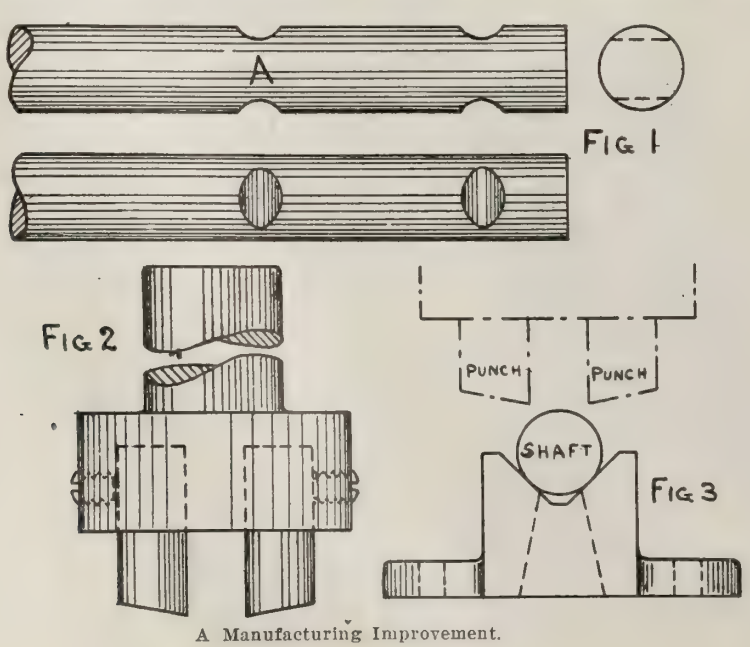
Unique Ways of Doing Things in the Machine Shop. Readers' Opinions Concerning Shop Practice. Data for Machinists. Contributions paid for.

A MANUFACTURING IMPROVEMENT.

By Donald A. Hampson.

THE shaft shown by three views in Fig. 1 and forming one of the parts of a certain special machine, has near one end a pair of notches cut for driving purposes. Each notch is double, making a total of four cuts. While their size, spacing and finish are within easy limits, a good deep notch is required, and at a low cost. The shafts are made from Jessop's carbon steel and to form the notches we tried both milling and grinding; either process, however, took considerable time when a thousand or more pieces had to be put through. We naturally were ready to consider any method that promised improvement. The suggestion was made that the notches be punched; and as we had an idle punch press, it was decided to rig it up; the cost of the tools not seeming excessive. A punch-holder was turned up from a piece of mild steel, and in the body two ½-inch holes were drilled and squared out for the punches. The latter were made from ½-inch drill rod and were secured in place by set screws, as shown in Fig. 2. A modified form of vee block served as a guide and support for the shaft while being punched, as may be clearly seen from Fig. 3. Lugs were provided for bolting down purposes, and directly under the punches the casting was cut to clear the latter and to give chip room. A slot was also cut in the middle of the block and a hardened steel piece inserted of the same shape as the rest of the vee, thus practically eliminating wear at this point.

For turning out the work quickly this outfit was the best we had tried—so good in fact that it was marked "Final." The punches had to be set so that both would strike at the same time, no clamp for the shaft being then necessary. The shafts, which were ⅝ inch in diameter, were pushed in against a stop and a stroke of the press formed notches A. They were then pulled forward until one of these notches engaged a latch held by a light spring, and a press on the treadle started the second stroke. The whole thing was as simple as could be, and required no changes to overcome initial defects. Punches were made up a dozen or two at a time, and seldom cost more than a dollar per thousand shafts notched. As will be observed, they are short and stiff, this being effected by keeping the clearance between the shaft and the punch holder as small as is practicable.

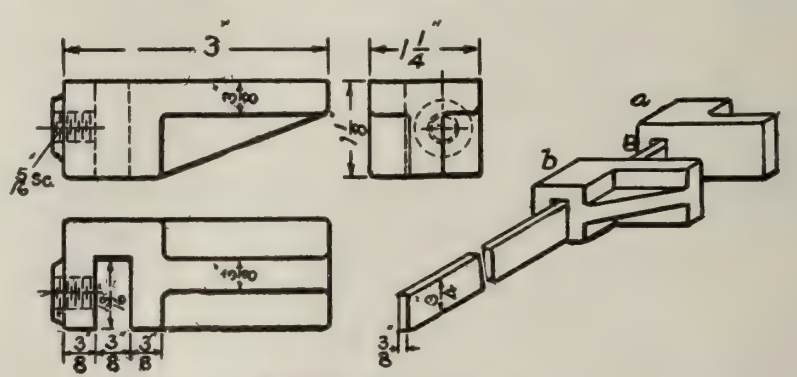


A Manufacturing Improvement.

A HANDY WORK HOLDER.

By J. E. Cooley.

ONE of the problems often met in connection with a drill press is a simple and quick method of holding work to be drilled, such as jig bodies, blocks, caps, etc. It often happens that there is no wrench handy that opens wide enough to take in the required piece, and the leverage from the handle of an ordinary wrench when resting against a stop is so short that drills are easily sprung. To overcome this difficulty, the device here shown was designed and will hold work of any width. The handle is 36 inches long, and when the end is placed against a stop, gives a powerful leverage, at the same time allowing the work to float and thus prevent the drill from being sprung. It consists of two cast iron jaws, "a" and "b," sliding on a piece of ⅜ x ¾ inch stock, and fastened by 5-16 inch set screws. The jaw, "a," can remain stationary and adjustment be made by jaw "b." The castings are, of course, made right and left handed.



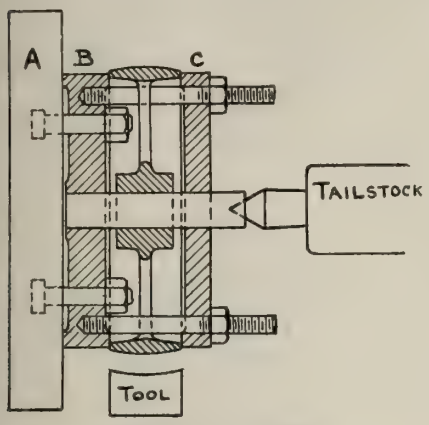
A Handy Work Holder.

RAPID PULLEY TURNING.

By J. H. W.

THE accompanying cut illustrates the method employed by A. B. Jardine & Co., Hespeler, Ont., for turning straight and crown-faced pulleys where the width does not exceed 4 inches. The hub is first faced and bored, and both edges of the rim are then faced true and square. Referring to the cut, A is the face-plate of an engine lathe to which a cast-iron plate, B, is attached by means

of T-headed bolts. This plate is bored out for a 1 3-16-inch mandrel, the outer end of which is supported by the tail-stock centre. The pulley is mounted on the mandrel, a sleeve being used if the bore of the hub exceeds 1 3-16 inches. It is then securely clamped to the plate B by means of the outer plate, C, and by



Rapid Pulley Turning.

long studs passing between the spokes. A flat profile tool, ground to the desired curvature and of the exact width of the pulley, is clamped to the slide rest and the job is then quickly put through. The time taken to turn a pulley 10 inches diameter by 2½ inches face is only four minutes.

The great advantage of this method of mounting the pulley is the high degree of rigidity secured, which enables a heavy cut to be taken. For this reason, the method is commonly employed by this firm, even when the pulley is too wide to admit of the use of a profile tool.

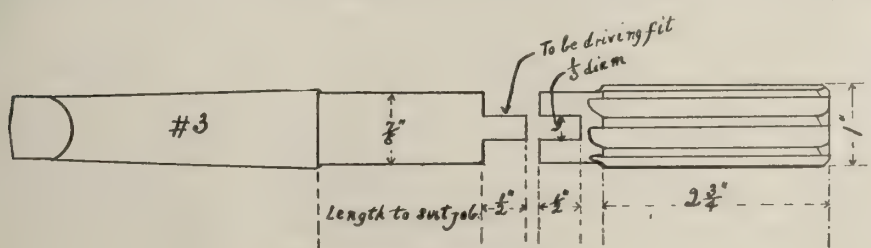
Standard plates and tools are kept on hand to suit various diameters and widths, and since their introduction a large saving of time has been effected.

ECONOMY IN HIGH-SPEED STEEL.

By E. Bates.

HEREWITH is shown one method of reducing the cost of making high-speed reamers, rose-bits, etc. The shank is made of machinery steel and rough turned to about .030 inch over size, the ends being milled as shown in the cut. The cutting portion of the reamer is of high-speed steel and is cut-off to length and also turned to about .030 inch over size. It is then put in the milling machine to be grooved and have the slot for the tongue on the shank cut. The width of this tongue is one-third the diameter of the shank and it is made a driving fit in the slot. The two parts having been assembled they are taken to a gas furnace and there brazed with copper wire, borax being used as a flux. When the correct brazing temperature has been reached, the tool is partly withdrawn from the furnace so that the joint cools, while the point reaches a hardening heat. It is then plunged into an oil bath, after which it is ready for grinding to size.

I have found that machining takes no longer by this method, as the shank is turned very much faster than when of high-speed steel; also the brazing and hardening take very little longer than when hardening an ordinary rose-bit. The amount of high-speed steel saved by this system of manufacture is quite a consideration where many rose-bits are used, especially if they are long ones. Moreover, it gives opportunities for using up short pieces that would otherwise be scrapped.



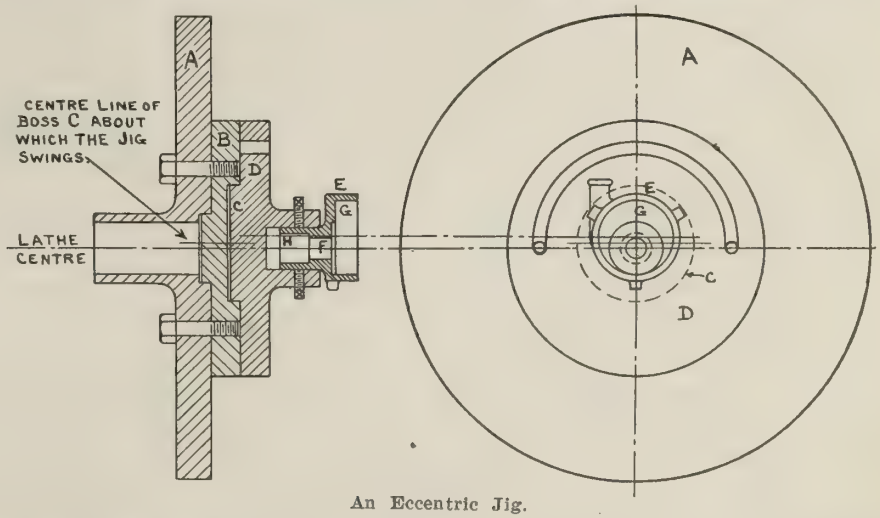
Economy in High Speed Steel.

AN ECCENTRIC JIG.

By John E. Davies.

THE following is a description of a jig designed by W. Moore and used by W. & J. G. Greey, Toronto, in boring and turning the casings of small centrifugal pumps designed for filling paint cans from a large tank. The operations to be performed on the casting, E, were: (1) to bore and counterbore the neck at F, and, (2) to bore and turn the inside of the shell G, which is eccentric with F. Before designing this jig, the job, of course, had to be set twice and we experienced considerable difficulty in keeping the faces in the same plane and in getting the same amount of eccentricity on each piece. However, the jig overcame all our troubles and enabled us to make a good job, every piece being alike. Moreover, the total time of setting up the work was reduced to 1½ minutes.

Referring to the drawing, A is the lathe face plate, which was first trued up and counterbored at centre. B is a cast-iron plate turned and fitted into the face plate as shown, and secured by cap screws and dowel pins. On the face of B, and eccentric with it, is a recess; the amount of its eccentricity being exactly half that of the job to be bored. The jig D is concentric with B but has a circular eccentric projection C which fits the aforementioned recess in face of B. The casting D is held in place by two cap screws, located at the ends of a semi-circular slot which allows the plate to be swung round through exactly half a circle when one of the cap screws is removed. Having set the work by means of four set screws, the neck F is first bored and counterbored. The cap screws securing D are then loosened and one removed, the plate then being swung through half a revolution, thus bringing the centre of the shell G in line with the lathe centre. The nose of the chuck is turned the same size as the bore of G, so that for the third operation, viz: boring and threading for a gland nut at H, the casting is simply turned round, placed on the nose of the chuck and secured by a yoke and two bolts. The plate D is then swung back to its original posi-



An Eccentric Jig.

tion bringing F once more central with the lathe spindle.

The semi-circular slot in D is, of course, not struck from the centre of plate D, but from the centre of the projection C on the back of it.

CUTTING KEYWAYS ON LATHE CHUCK WORK.

By F. Cotton.

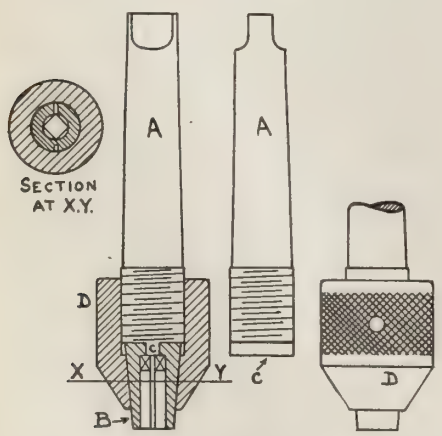
HAVING occasion to cut keyways in some chuck work and having nothing but a lathe on which to do the job, I put a 24-inch pulley on my main line-shaft and connected it by a 1½-inch belt to the core pulley on the end of the thread-cutting gear spindle. I then chucked the work and blocked the chuck to prevent it from turning. Having clamped the tool in the tool post, I next closed the nut on the lead screw, running the carriage back by hand after each cut. In this way I cut a 1-inch by 6-inch keyway in 40 minutes.

A POSITIVE DRIVE TAPPING CHUCK.

By John E. Davies.

THIS positive drive chuck consists of three pieces only, and was designed especially for tapping nuts or any hole passing right through the work. For tapping blind holes, a friction drive is perhaps preferable, since there is then less chance of breaking the tap if the latter is carelessly allowed to reach the bottom of the hole. The illustration clearly shows the construction of the chuck. A is the shank turned to a standard Morse taper and having at its lower end (below the threaded portion) a driving tongue, C, which fits into a corresponding slot in the collet, B. This collet is of hardened steel bored out and squared at the top to take the tap. It is sawn completely through on one side and partly through on the other, to enable it to take a firm grip of the tap when the chuck is tightened up; this is shown in the section on X.Y. D is a round knurled nut threaded to fit the shank and bored out taper at its lower end to fit the outside of the collet. When the tap is inserted, a slight turn of this nut suffices to lock it securely, holes being provided in the periphery of the nut for the insertion of a locking bar.

To accommodate different sizes of taps a complete set of collets is provided, each one being bored and squared to fit its own tap, but all having the same diameter and taper on the outside.



Positive Drive Tapping Chuck.

WATCH THE LABEL ON YOUR PAPER.

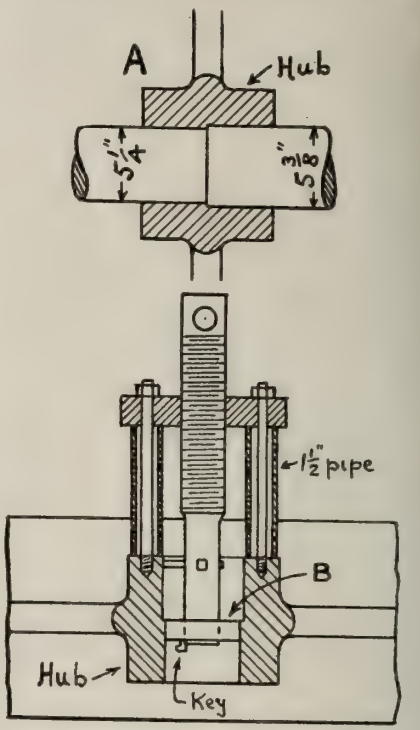
So heavy has become the work in the subscription and circulation departments of our various papers that we are unable adequately to keep up with the work of sending receipts to all subscribers for subscriptions received. Some time ago, because of this congestion, we were forced to select a new plan with our trade papers by notifying our readers who sent in money for subscriptions to watch the address label of their paper and see that the date of expiry of subscription was changed. This plan has worked well with the papers which adopted the scheme, the changing of the date being sufficient notification to the subscriber that his subscription had been received.

In future, instead of sending out receipts for money paid on subscriptions we will simply change the expiry date on the paper going to the subscriber. If your paper does not have the label changed on the next or following issue after payment of subscription, drop us a post card and the error will be rectified immediately. Watch the label on your paper.—The Canadian Machinery.

REBORING A LARGE PULLEY.

By F. Cotton.

HAVING to rebore a pulley 6 feet in diameter to fit two different sizes of shafting as shown in the sketch at A, and there being no lathe large enough for the job, I rigged up a boring tool in the following manner. With the pulley lying flat on the floor, I first tapped into the hub four ¾-inch studs, 10 inches long, and over these I placed pieces of 1½-inch wrought iron pipe. These supported a circular plate 2 inches thick, having at its centre a hole tapped out to 3 inches diameter, 16 threads per inch. To fit this hole I turned and threaded a boring bar as shown in the sketch. I next turned up a piece B, 5¼ inches diameter to fit the bore of the pulley, and keyed this to the end of the boring bar to act as a guide. The tool was made of ½-inch square self-hardening steel and



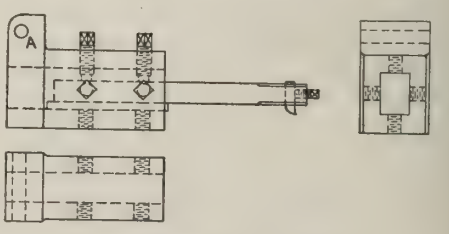
Reboring a Large Pulley.

the bar was revolved by a pinch bar inserted in a 1⅜-inch hole near the top. By these means I managed to complete the job in eight hours.

SPECIAL SHAPER TOOL BOX.

By A. E. W.

THE tool box here shown is intended to take the place of the usual cranked tool bar when doing such work as keyseating a gear wheel on a shaper or planing a job that will not pass under the crossbar of the planing machine. It consists of a grey iron casting in which the tool bar is clamped by set screws,



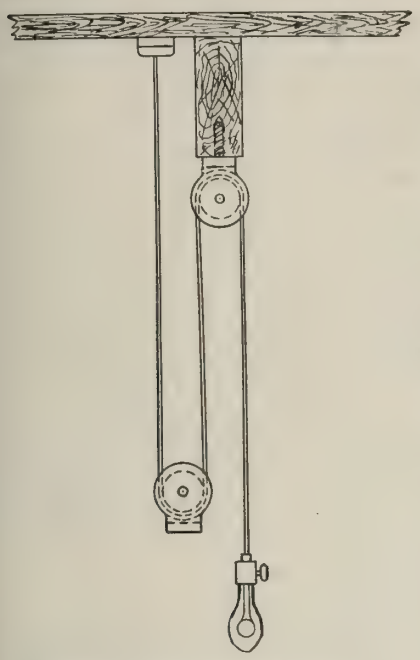
Special Shaper Tool Box.

the construction being clearly shown in the sketch. When about to be used, it is substituted for the ordinary tool box in the shaper or planer, being held in place in the usual way by the hinge pin A. Such a device can be cheaply made up and is more rigid than a cranked tool.

WOODEN PULLEYS FOR DROP LIGHTS.

By J. H. W.

THE Stevens Company, Ltd., Galt, Ont., use numbers of counterweight drop lights to illuminate their work benches and vises, each lamp being provided with a sufficient length of cord to enable the recesses of cupboards and shelves below the bench to be explored. Wooden pulleys—see sketch—of



Wooden Pulleys for Drop Lights.

about 3 inches diameter are used instead of the small porcelain or metal pulleys usually met with. This not only reduces friction, but also helps to prevent the rubber insulation from cracking and perishing as it so often does when bent over pulleys of small diameter. If the lower pulley is too light to balance the lamp, a few washers or a short piece of pipe are hung from it.

DEATH OF FRANCIS H. STILLMAN.

Francis H. Stillman, president of the Watson-Stillman Co., and a prominent figure in machine tool and engineering industries, died suddenly, February 18th, at his late residence, Rodney street, Brooklyn, in his sixty-second year. The day before his death, he was at his office as usual and apparently in the best of health. The deceased gentleman was born in New York on February 20, 1850, and graduated from Yale, in the class of 1874, with the degree of B.Sc. He was a member of the Hanover Club of Brooklyn, the Engineers' Club, the American Society of Mechanical Engineers, and a director of the National Association of Manufacturers. He organized and was first president of the Machinery Club of New York, and was also first president of the National Trades Association. In addition to being president of the Watson-Stillman Company at the time of his death, he was also president of the Bridgeport Motor Co., and of the Peouannock Commercial Co., and a director in other manufacturing firms.

INTERNATIONAL SAFETY CONGRESS.

The new American idea of the safety engineer, an accident prevention specialist, will be brought to the notice of world industrialists at an international safety congress to be held in Milan, Italy, for five days, beginning May 27, 1912. This congress, the first of its kind of international scope ever held, will be for the purpose of setting in motion a world-wide movement for the conservation of human life in industry.

The American Museum of Safety, 29 West Thirty-ninth street, New York, is making preparations so that the United States will be well represented. An American national committee has been selected by the American museum to cooperate with the international body and to promote the American ideas and views at the congress. Dr. W. H. Tolman, director of the American Museum of Safety, and other members of the committee, will attend.

The following are some of the papers which will be read:—

"The Safety Engineer on a Large Transportation System," by Dr. W. H. Tolman, chairman, American national committee; "How the New York Edison Safeguards the Lives and Limbs of Its Employes," by Arthur Williams; "The Work of the Safety Committee of the United States Steel Corporation;" "Safeguarding the Traveling Public and Protecting the Employes of the Electric Street Railway Association;" "Proper Illumination and Accident Prevention," by J. V. Langsingh, president of the Illuminating Engineering Society.—Ex.

DOMINION STEEL CORPORATION.

THE development of the various industries comprising the Dominion Steel Corporation is to be of the most extensive kind during the present year. The statement was made recently that the company was buying land and would establish a large manufacturing plant on the Island of Montreal. Investigation showed this rumor to be unfounded, but the important fact was revealed during the enquiry that the Steel Corporation will locate a vast entrepot on the canal near St. Ann's Church, and that already a good area of land has been acquired for its future wants. This enterprise means that the company is about to make Montreal a distributing point for their manufactured goods, such as nails, rods and, in fact, all the wire goods which are so soon to be turned out by the large plant that is now being constructed at Sydney for this purpose.

It is also announced that the Steel Corporation will have steamers of their own in the near future not only for the purpose of bringing coal to Montreal, as is the case already, but to carry the products of their improved plant at Sydney up through the canals and to the various points of population and consumption between here and Port Arthur and on to Western Canada. The policy of the corporation will be of the most aggressive character, not only in the way of manufacturing, but in the distribution of their products. The directors, who are extremely satisfied over the present situation, declare that their industry is but in its infancy, and that the extent of the future development of the company's plans cannot possibly be estimated by those who who have not visited the works under way and in contemplation at Sydney.

The financial side of the company's operations have been made interesting by the statement that the company has already been placed in possession of a part of the money coming to it from the sale of $3,500,000 preferred stock to Speyers & Co., the balance to be paid in the near future. As has already been announced, the same financial house will take the other half of the seven million dollar issue when the requirements of the Steel and Coal Companies require the money for the betterment of their plants.

NEW C. P. R. SHOPS AT CALGARY.

The contract for these shops has been let, the price being in the neighborhood of $2,750,000. Orders for material are now being placed, and construction will commence as soon as possible. An endeavor will be made to have the shops in operation by December 1st next. The contract has been awarded to the Westinghouse, Church, Kerr Co., Pittsburg, and calls for the design and construction of locomotive, machine, boiler, blacksmith, pattern, coach, freight, car repair and paint shops; also foundry planing mill, power house, stores and office buildings.

A novel method of overcoming the heating of a locomotive journal bearing was recently described in a trade journal. The brass bearing, which continually ran hot, was raised from the axle and a piece of thin sheet lead inserted between the two. The axle was then lowered on to the bearing and allowed to run as usual. The lead was thus worked into the pores of the brass and the heating ceased. The efficiency of lead in a bearing thus becomes apparent.

Mechanical Drawing and Sketching for Machinists*

By B. P.

A Series of Progressive Lessons Designed to Familiarize Engineers With the Use of the Apparatus Necessary to Make Simple Drawings, to Encourage Them to Realize How Important a Factor it is of Their Equipment, as Well as Being a Profitable Pastime.

THE end of winter and the coming of spring being within measurable distance, it is perhaps only natural that the average man should begin to find evening studies somewhat irksome. In sympathy with this feeling it has been decided to discontinue the present course shortly, and the final instalment will be published in the April issue of Canadian Machinery.

The subject given this month is an ordinary shaft bearing, often called a pedestal or pillow-block, and may be drawn to a scale of either 4 or 6 inches to the foot. The bearing proper is of bronze and is 4 inches diameter by 6 inches long. It is of course split across the horizontal centre line and is prevented from turning by projections top and bottom at the middle of its width. Both half-brasses are cast from the same pattern, a detail of one-half being given in Fig. 2. It will be noticed that these are slightly thicker at the bottom than at the sides and that they fit into the pedestal near the two ends only, the middle part being cast clear and left rough. The pedestal is cast similarly, as the plan view in Fig. 1 clearly shows. In this plan the left-hand half shows a view looking down on the top of the cap or cover, while the right hand half shows a view of the pedestal with the cover removed. The cap and pedestal are of cast iron, and, as seen in the elevation and end view, the former has a boss on the top into which a lubricator may be screwed, the oil passage being drilled through the cap and the projection on top of the brass. These details should be added by the student when making the drawing.

Fitting strips are provided all round the base of the pedestal and across its centre, while to provide for longitudinal adjustment, the bolt holes in the base are elongated. When the brass is worn, adjustment is made by filing across the joint, the cap being tightened down to suit, by means of the two 1¼ inch bolts. In the present example, the holes for these bolts are drilled, while the recesses for their square heads are cored out in the mold. Sometimes, however, the bolt holes, as well as the head recesses are cored, the former being made ⅛ inch larger than the diameter of the bolts.

No dotted lines have been shown, but the student should add these, where they may be useful in making the drawing more easily read. Practically all the necessary dimensions have been given either in Fig. 1 or Fig. 2, so that by consulting both figures no difficulty should be experienced in making a complete drawing.

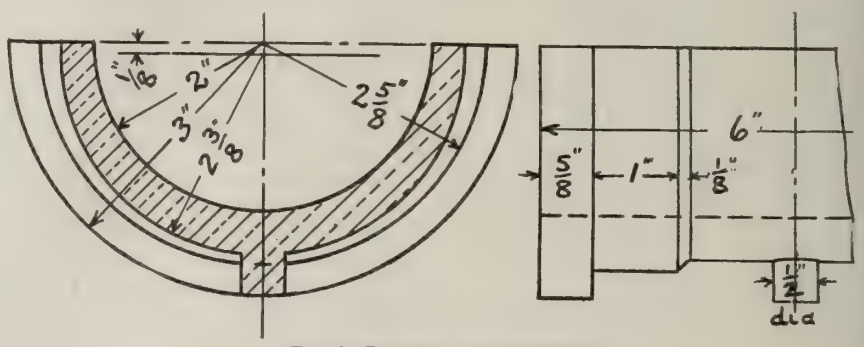


Fig. 2—Drawing and Sketching.

Exercise: — Draw complete separate views of every part of the plummer block shown in Fig. 1, showing clearly the fitting strips below the base.

Shop Sketches.

It is hoped that readers have followed out the suggestions made in the lesson of November last and have assiduously practised making shop sketches; and further, have afterwards made finished drawings from these sketches, since the latter process serves better than anything to show up the weakness or strength of the sketches.

The principal requirements of a good sketch are accuracy, completeness and clearness. The latter quality is all important, and care must be taken to make all sketches so clear that, even if laid aside for months or years, they may be readily understood when consulted again, without trusting to memory. The beginner too often makes sketches hurriedly and carelessly, carrying certain details "in his head" until the time comes to make the finished drawing. He may then find that his memory has played him false, and he is perhaps inable to gain access a second time to the object he was sketching, which may have gone to the scrap heap or cupola. Hence, the great importance of completeness and clearness in the sketches. Use an H or HB pencil in making them, and a 3H or 4H for the finished drawings.

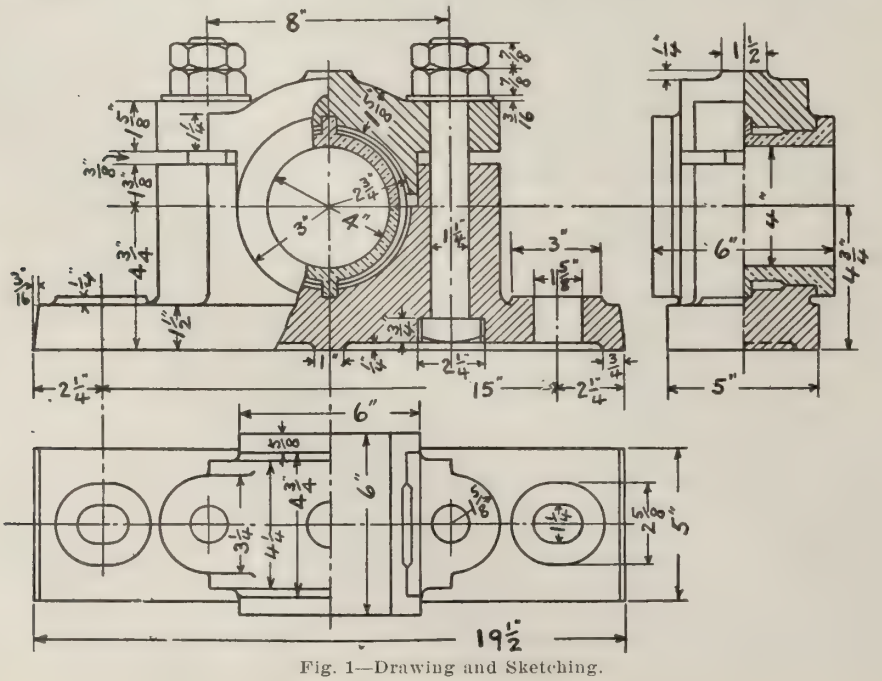

Fig. 1—Drawing and Sketching.

* Thirteenth of a series of an instruction course.

ELEVATOR CONTRACT.

The contract for the elevators in the new C.P.R. office building, corner of King and Yonge streets, Toronto, has been awarded to the John McDougal, Caledonian Ironworks Co., Montreal.

There will be five hydraulic direct plunger elevators with the necessary pumping and signaling equipment. Three of these elevators for passenger service will have a lift of 188 feet, and one of them a lift of 199 feet. The fifth, used for ashes, etc., will have a lesser lift. The passenger elevators will be provided with every modern device to secure speed and safety in operation, including automatic limit stops, which, independently of the operator, will slow the speed down gradually at the top or bottom without shock or vibration. They will be operated by Worthington compound steam pumps, and will be directed by an elaborate flash light signal system. In general features, these elevators will be similar to those built by the same company for the new C.P.R. Windsor Station, Montreal.

RAILROAD EQUIPMENT FIGURES FOR 1911.

THE year 1911 was a particularly lean one for equipment companies. The dull business that marked the trade at the end of 1910 continued almost throughout the year. Railroads deferred their buying of cars and other equipment till the latest possible moment on account of the general timidity that was apparent throughout the business world, and all the equipment concerns were therefore obliged to curtail operations and to cut prices in an attempt to induce orders.

Towards the middle of the year most of the companies were operating at much less than half, and in some cases as low as one-quarter of capacity. From January to June the total of car orders placed throughout the country was under 50,000. In the third quarter about 22,000 cars were ordered, and it was only the quickened buying movement starting early in November that enabled the 100,000 mark to be reached.

In November alone more than 40,000 cars were ordered by the railroads and other companies. These, however, were taken at prices that allowed at best little profit to the manufacturer and many contracts are stated to have been taken at actually below cost in order to keep plants running. The price of steel freight cars went down as low as $750 per car, but even with the low prices then ruling for steel plates it was impossible for car builders to make a profit at this figure.

Car and Locomotive Orders.

The number of cars and locomotives ordered in the United States and Canada during the year, according to the Railway Age Gazette's annual table, was:—Freight cars, 113,117; passenger cars, 2,623, and locomotives, 2,850. Of the freight and passenger cars slightly under 100,000 were placed with builders in the United States. These figures compare with the orders placed for the 10 years previous as follows:—

Year	Freight cars	Passenger cars	Locomotives
1910	141,204	3,881	3,787
1909	189,360	4,514	3,350
1908	62,669	1,319	1,182
1907	151,711	1,791	3,482
1906	310,315	3,402	5,642
1905	341,315	3,289	6,265
1904	136,561	2,213	2,538
1903	138,936	2,310	3,283
1902	195,248	2,459	4,665
1901	193,439	2,879	4,340

READER, WHAT DO YOU KNOW?

Among readers of Canadian Machinery there is a clearly defined sincerity of desire to know how each overcomes the daily tasks of the machine, pattern and blacksmith shops, the foundry and boiler shops. It is believed that your methods and devices, while good, may be improved, and thereby made more valuable if you publish them, so that other brains may work on them. We will provide the setting and pay you for the material. When your fellow tradesman puts the superstructure on your foundation, we pay him and pass the "kink" on to you, free. Get into the game.

It will be seen from the above table that the number of cars ordered during 1911 was the lowest since 1900, with the exception of 1908, as the figures given above for 1903 are for cars ordered from manufacturers in the United States only.

Cars and Locomotives Built.

The number of cars and locomotives built during 1911 was:—Freight cars 72,161; passenger cars 4,246; locomotives 3,530. The following is a table of the number of cars and locomotives built in the United States and Canada in the previous six years:

Year	Freight cars	Passenger cars	Locomotives
1910	180,945	4,412	4,755
1909	93,570	2,849	2,887
1908	76,555	1,716	2,342
1907	284,188	5,457	7,362
1906	240,593	3,167	6,952
1905	165,155	2,551	5,491

The actual number of cars built during the year 1911 falls considerably below the number ordered. This is due to the fact that the largest part of the ordering was done toward the end of the year. These cars were not of course delivered and the new year finds most of the companies with a fair volume of unfilled orders on their books.

1912 Outlook.

The equipment companies are beginning the year with a much better outlook than that of last year. Their operations now range from 45 to 75 per cent. of capacity. Besides the amount of unfilled orders there is every reason to expect more steady buying in the near future. Sentiment everywhere is better and the railroads are showing a greater disposition to fill their needs. Prices also are slowly returning to the normal, as the manufacturers are now in a stronger position than during 1911.—Exchange.

Personal

Mr. A. S. Herbert, Canadian manager Siemens Bros.' Dynamo Works, has left for England on a business trip.

Mr. T. R. Price has joined the sales staff of the Packard Electric Company with headquarters at Toronto.

Mr. L. W. Morden has been appointed sales engineer of the Packard Electric Company with headquarters at Toronto.

Mr. O. Larsen, late mechanical engineer with the National Bridge Co., and previously connected with Miller Bros. & Toms, and the Montreal Locomotive Works, took over the management of the Pontbriand Co., of Sorel, at the beginning of the year.

W. A. Glasgow has resigned as works manager of the Canadian Steel Foundries, Ltd., at Welland, Ont., to enter other lines of business.

Mr. E. R. Mathewson, general manager of the Anaconda Smelting Works, has been awarded the gold medal of the Institution of Mining and Metallurgy, London, England. Mr. Mathewson is a native of Montreal and a graduate of McGill University.

When drilling very hard metals, it sometimes happens that no amount of lubricating oil or cutting compound will keep the drill cool. In such cases turpentine will be found effective in causing the drill to "bite" and also retain its temper.

FOUNDRY PRACTICE AND EQUIPMENT

Practical Articles for Canadian Foundrymen and Pattern Makers, and News of Foundrymen's and Allied Associations. Contributions Invited.

MODERN FOUNDRY PRACTICE*

By Hugh Munro, B.Sc., M.I., Mech. E.*

THE iron foundry is the subject of a great deal of attention on the part of engineers at the present time. Iron founders are charged with the crime of not having made use of the help which science is able to give them, and are said to have made little or no advance relative to the other branches of the iron industry. It is true that mild steel, with predetermined physical properties, can be produced with far more certainty than cast iron of predetermined physical properties. During the conversion of iron into steel, it is under thorough control in melting; its chemical constituents can be adjusted, and its physical properties can be subsequently modified within limits by heat treatment. When melting iron in the cupola, on the other hand, the chemical composition can only be approximately arrived at by mixing two or more brands of iron while charging. During its passage through the cupola, some of the constituents are reduced in quantity, being partly burned out by the blast; others, such as sulphur, are increased by absorption from the coke. The intensity of the blast, the composition of the coke, the nature of the mold into which the iron is subsequently poured, and the temperature at which it is poured, all influence the success of the casting. If heat treatment is applied to ordinary iron castings they usually deteriorate in quality, and finally, if you do get the chemical composition you aimed at, you don't necessarily always get the same physical properties attending it.

The moulder and the chemist must work together to secure success. Scientific control in the foundry, of which so much has been said and written of late, means a great deal more than most people think who advocate it. According to this theory, if a chemist chooses the proper irons for any particular job, all will be well; but this is very far from being the case as I shall show later on. Scientific control in the iron foundry really means more or less investigation into the design of the casting, into the composition of the metal, the temperature of pouring, the composition and tempering of the sand, and the construction, venting, and gateing of the mould. Every new and complicated pattern which comes into the foundry must be considered on its merits. No matter how complicated a casting may be, if there are large numbers to be made, they can, after a while, be turned out with very few wasters by almost any intelligent moulder, but during the early stages of manufacture, and until the peculiarities of that particular pattern come to be known there are often far more wasters than good ones.

A new and intricate pattern often leads to a course of original research on the part of the moulder before he finds out the best way of doing things. If the iron foundry is to be subject to scientific control, it is not sufficient to choose only iron, coke and sand, scientifically. The blast, the temperature of the metal and the construction of the moulds must also be investigated in detail. This is comparatively easy when there is much repeat work, but in an average jobbing foundry where different patterns are in use every day every individual moulder must, or ought to be, a scientist.

Features of Foundry Practice.

Modern foundry practice covers such a large field that in a short lecture such as this, only a few of the chief features can be dealt with. I propose to review briefly the following points:

(1) Melting Iron.
(2) Shrinkage of Cast Iron.
(3) Defects in Castings—Wasters.
(4) Methods of moulding—Moulding Machines.
(5) Foundry Outfit.
(6) Constituents of Cast Iron.

Melting.—For foundry purposes iron is melted either in the air furnace, the cupola, or in some kind of crucible furnace, but the latter is not used to any great extent. Of the other two, although a better quality of iron is obtained from the air furnace, it is not in general use because it melts slowly, and is expensive to operate. The metal is fairly well under control, and its composition may be varied during melting to suit the work in hand. Carbon and silicon may be burned out, or other constituents added exactly as in an open hearth furnace, which in fact it is.

The air furnace is used mostly for large and important castings, such as chilled rolls, where it is essential that the castings should be homogenous throughout. A large quantity of metal of uniform composition can be obtained from this furnace much more easily than from the cupola. Most of the iron for foundry purposes is melted in the cupola. For melting iron cheaply and rapidly, this furnace has no equal, but, unfortunately, after the iron goes into it, there is practically no control over its composition until it is tapped out again into the ladle, and then the time at one's disposal is so limited that little can be done to improve the metal.

The cupola consists essentially of a vertical steel cylinder lined with fire brick. It may vary from 18 inches to 12 feet diameter. The tuyeres through which blast is admitted are usually set about 18 inches above the bottom, and spaced equally round the circumference. In large cupolas, there may be two or three rows of tuyeres one above the other. The iron is charged through a door 6 to 20 feet above the tuyeres. American cupolas have usually a drop bottom, so that when the melt is over, the unburned coke may be dropped out. British cupolas have usually solid bottoms, and the unburned coke is raked out.

When the iron is melted it drops down past the tuyeres and lies in the well of the furnace until it is drawn off, but some cupolas have a receiver into which the metal flows as it is melted. The receiver has a few advantages: (a)—A larger quantity of molten iron can be kept hot there than in the well of the cupolas when it is wanted for a large cast: (b)—The metal is drawn away out of contact with the coke in the cupola from which it absorbs sulphur: (c)—The metal is said to be better mixed in the receiver than if it were collected in the ladle. A receiver is, however, a little troublesome to keep in good condition, and the iron which is first melted may have to be cast into pigs as it is often too cold to be used for castings. The slag is tapped out through a hole higher up than the tap hole.

The cupola is charged by filling with coke up to 18 or 20 inches above the tuyeres, and thereafter iron and coke are charged alternately in thin layers up to the charging door. Melting does not take place throughout the whole charge, but only in a short depth extending from the tuyeres to about 18 inches above them. This is known as the melting zone, and it varies in position with the strength of the blast. When a cupola is blown out, the position of the melting zone can be seen, the

*Lecture before the Glasgow University Engineering Society, December, 1911.

** Superintendent Glenfield & Kennedy, Kilmarnock, Scotland.

firebrick being melted away at this point where the heat is greatest. A small quantity of lime is put in with the iron and coke in order to flux the impurities in the charge. Blast is supplied by Root's blowers, or by centrifugal fans, the former I think being the better of the two. The quantity of coke per ton of iron depends to a great extent on the nature of the work. Iron for light work must be more fluid than that for heavy work in order that it may run freely and fill all parts of the mold. Consequently iron for light work must be hotter than for heavy work, and more coke is therefore required for melting it. Too much coke, however, may have no other effect than that of making the furnace melt more slowly without producing hotter iron. For instance, if the first coke charge were just up to the top of the melting zone with the iron just above it, melting would begin a few minutes after the blast was turned on; but if the top of the first coke charge was 12 inches above the melting zone this amount of coke would have to be burned away before melting began, and it would be wasted. When the blast leaves the melting zone it consists of nitrogen and C.O. In many cupolas, this C.O. passes up through the coke and burns when it meets the atmosphere at the charging door or at the top of the cupola. If a second row of small tuyeres be placed a few feet above the melting zone, this gas can be burned in the furnace so as to heat the charge and effect great economy in coke. It is, of course, important that the oxygen supplied by these auxiliary tuyeres should not combine with the coke. The blast from these tuyeres should, therefore, be not intense and local, but rather, low in pressure and diffused over as large an area as possible.

The blast for a cupola may vary from 8 to 20 inches of water, and good results can be obtained from both extreme pressures, depending on the nature of the coke and rate of melting. The amount of iron melted per ton of coke varies from 8 to 12 tons, and here, again, either extreme may be good practice, depending on what the iron is required for. Limestone may be used up to 60 lbs. per ton of iron. The coke should be hard and free from sulphur to give good results. An average composition of good coke is as follows:—

Ash, 6-10 p.c. S., .5 to 1 p.c. H.O., 1 p.c. Carbon, 80-92 p.c. Volatile, 1 p.c.

Moisture in coke does not seem to affect the iron in any way, as it is all evaporated before the coke reaches the melting zone. Limestone should be free from Al. and Si. Iron in passing through the cupola undergoes certain variations in its chemical and physical structure. A small proportion of silicon and manganese is burned out by the blast, sulphur is absorbed from the coke, and some G.C. changes to C.C. Phosphorus usually undergoes no change. The iron becomes harder and denser, and closer in grain after re-melting. It shrinks more, and an open iron usually becomes closer and stronger. A small percentage of iron passes into the slag and is lost, but it is difficult to say how much this amounts to. When an iron of a definite composition is required, the correct quantity of each brand is taken for the charge and allowance is made for the changes which take place in the cupola.

It is becoming a common practice to melt mild steel in the cupola along with iron. The resulting metal (known in America as semi-steel) is lower in Si., G.C., and total carbon than if all cast iron were used in the charge. Any quantity of steel up to 25 per cent. may be used. The proper method of using it, however, is not quite understood, and it is rather risky to use it in large proportions on machined work, as it tends to produce blow holes. Generally speaking, it strengthens and toughens the iron, makes it closer in grain and harder. The results sought by the use of steel can usually be got by choosing proper brands of iron. The proper mixture of iron to use for different classes of castings is a most important part of the iron founder's art. In all foundries some attempt is made to put into a mold the iron most suited for the casting. Two or three brands of pig iron are used and mixed with scrap in the proper proportions while they are being charged. A common charge for every day work is half scrap and half No. 3 pig. For soft castings, easily machined, some of No. 1 pig is put in along with the scrap, while the proportion of No. 3 is reduced. Blast of low pressure tends to produce softer castings than a high pressure blast. In an ordinary jobbing foundry where all classes of work are being made, several different qualities of iron may be required in the course of a melt of three or four hours' duration.

Shrinkage.

During cooling cast iron contracts both in the fluid and in the solid state. The former is termed fluid contraction, and the latter is technically known as shrinkage. The amount of shrinkage of cast iron is pretty well known. It amounts to about $\frac{1}{8}$ inch per foot, and is allowed for by making the pattern that amount larger than the casting. Shrinkage varies considerably, according to circumstances. It is greater in thin castings than in thick ones; in quickly cooled castings than in castings slowly cooled, and in green sand castings than in those made in dry sand or loam. Increase of Mn., C.C., and S. increase shrinkage, while increase of G.C., Si., and P. diminish shrinkage; and white iron shrinks more than grey iron.

If castings are unequally proportioned, severe internal stresses are set up in them owing to unequal shrinkage. For instance, in a wheel with a heavy boss and a light rim the boss contracts last, and in doing so puts a severe tensile stress on the arms, often causing them to break. Wheel arms, for this reason, are often curved, or the boss is split to eliminate cooling stresses due to unequal contraction, and afterwards hooped. Long castings such as lathe beds, in which one side of the casting is thick and the other side thin, bend in cooling, and the pattern should be made with an initial set so that the casting may come out straight. As the most extreme example I have ever come across, I may mention a casting, 36 feet long, weighing 14 tons, and having one side 3 inches and the other $1\frac{1}{4}$ inches thick, which bent 3 inches in cooling. The pattern had been made with a camber of $2\frac{3}{4}$ inches in the opposite direction, so that the casting when finished was only $\frac{1}{4}$ inch bent. It was concave on the thick side. In large thin castings it is necessary to loosen the cores soon after pouring in order to allow the casting to shrink freely; if this is not done the core may prevent the iron from shrinking and cause it to crack.

According to a series of experiments made by Keep, under the auspices of the Am. Soc. M.E., cast iron does not shrink uniformly from the time it becomes solid. Just after solidification it expands; then contracts, expands again, and contracts, and sometimes it may expand a third time before the final and regular shrinkage begins. During this period of expansion and contraction, a great change takes place in the internal structure of the metal. Solid cast iron, as you know, may contain up to 3 per cent. free carbon in the graphitic form. This is assumed to be in solution while the iron is fluid, and is generally supposed to assume the graphitic form during the act of solidification. From the above named experiments, it has been found that when cast iron first solidifies, the carbon is still combined with the iron, and not until the final shrinkage begins has all the graphitic carbon separated out. These expansions and contractions, and the change from C.C. to G.C. extend over a varying period of time, depending, of course, on the rate of cooling of the casting.

If the iron is cooled quickly, the C.C. has not got time to separate out, the casting is hard and does not contain much if any, graphitic carbon, while the alternate expansion and contraction just after solidification are much less pro-

nounced than when the casting is cooled slowly.

Since cast iron first expands on cooling from the fluid state, it follows that if molten iron is cast around an iron core, this core may be withdrawn easily while the iron is hot, and before the ultimate contraction has commenced. Keep's experiments also indicate, that, if molten iron is cast in chills and taken out of the chill as soon as it has solidified, the casting is not chilled very hard.

Fluid Shrinkage.

Although solid shrinkage is so complex in its operations, it is easy to make allowance for it. Fluid contraction is much more difficult to deal with. The defects in castings known as draw holes, shrink holes, sponginess, are due almost wholly to fluid contraction.

The moulder has his own methods—not always successful, for counteracting the effects of this vice in cast iron, but a great deal may also be done in the drawing office to lessen opportunities for it to exert its influence. Unfortunately for the founder, it is too frequently impossible for the drawing office to design castings in which fluid contraction can be wholly avoided. If a casting is of such a shape that part of it remains fluid after the parts surrounding it have become solid, the fluid part contracts while solidifying, and, having no reservoir of fluid iron to draw from, a hollow space forms in the casting and is termed a draw hole or shrink hole. More frequently, instead of a hole, the metal becomes soft and open in texture, and allows water to pass through it easily, and the iron is then said to be spongy. The drawing office can do its share towards lessening sponginess by designing castings of as uniform a thickness as possible. The metallurgist does his part in finding an iron with small fluid contraction. The moulder meets the difficulty in various ways, the most common of which is "feeding." Feeding consists in putting risers or feeders on the thick parts of the casting, filling these feeders with hot metal, and keeping a passage open between the iron in them and the interior of the casting until the latter has solidified. Rods are worked up and down in these feeders to prevent them solidifying, and in large castings hot iron is poured in to make up the loss caused by contraction. If the casting is a plain cylinder, a feeding head or sinking head may be cast on the top of it. This head is thicker than the casting ; it remains fluid longer, and feeds the casting automatically. The head is afterwards cut off. If feeding by hand be carried to excess a draw hole may appear on the surface instead of in the interior of the casting. It is not always possible to feed the thick part of a casting, therefore, it is common practice to chill it, that is, the mould at the thick part is lined with cast iron blocks which cause this part of the casting to solidify first, or cast iron chills of a special shape may be stuck into the mould and project right into the thick part of the casting. These chills unite with the molten metal and become part of the casting while the part which supported it in the mould is afterwards broken off. The open texture of cast iron which is frequently seen in thick castings is not always due to fluid contraction, but may be caused by too much silicon, or slow cooling.

Very little is known about fluid contraction. Some irons no doubt possess it to a lesser degree than others, but we don't know how it is affected by the chemical composition of the iron. When thick castings have got to be drilled, it is often a difficult matter to prevent them leaking afterwards under high pressure. I have found that if a cast iron core is cast in and afterwards drilled out, this trouble of leaking disappears. A sand core could be used, but would be likely to get washed away when the mould is being filled.

NEW HOT GALVANIZING PROCESS.

A new hot galvanizing process patented by Prof. Chas. F. Burgess, of the University of Wisconsin, Madison, Wis., differs from other processes heretofore in use, in that an alloy of zinc and iron forms the coating instead of pure zinc. The patents have been assigned to the United States Sherardizing Co., New Castle, Pa.

The process consists in using an alloy of zinc and iron for coating the iron or steel goods to be galvanized. The alloy is made by allowing thin sheet iron to dissolve in molten zinc until an alloy of about 92 per cent. zinc and 8 per cent. iron is obtained. This alloy is quite brittle and is powdered or granulated. The articles to be galvanized are placed in an iron tumbling barrel with this zinc-iron alloy in the granular form and heated while the tumbling is going on. The heat is maintained at about 850 degs. F. The heating is continued for two hours or more. It has been found expedient in the process to supply zinc so that the iron content of the alloy will not increase. Zinc dross (containing about 3 per cent. of iron) is, therefore, introduced into the barrel in the form of large lumps and the tumbling allowed to proceed. These lumps become readily broken up in the hot barrel and mix with the granulated zinc and iron alloy.

The coating of zinc and iron alloy obtained on iron and steel goods by this process is, the inventor says, very dense and silver-white in color. It is electropositive with respect to iron, but not to the extent that pure zinc is. The inventor says that this is quite an advantage, as the coating, when exposed to the atmosphere, is not corroded as rapidly as zinc, and yet it protects the iron or steel underneath equally as well.

If desired, the zinc and iron alloy may be made by using zinc dross entirely and placing it in the barrel along with the goods to be galvanized. The heat and tumbling break up the lumps. To supply the iron, small pieces of scrap iron are introduced with the zinc dross.—Ex.

MELTING BRONZE IN A CUPOLA

Mr. P. D. Malloy, writing in the "Obermayer Bulletin," says: "I have taken out a heat of bronze metal from a No. 5 Whiting cupola by charging the latter in the same manner as for a heat of grey iron. I put on the blast at 2.30 p.m., and in 25 minutes, tapped the cupola and took off 1,350 pounds. Swinging the crane ladle around to the mold before pouring, holding ladle twenty minutes, then swinging crane ladle back to the cupola, I tapped out again from 300 to 400 pounds. It took just one hour to take off the heat, containing from 1,600 to 1,700 pounds of metal. In this heat the shrinkage was very low. By regulating the tuyeres, there is no trouble in running out the metal at any heat necessary. I carried the blast at from 7 to 7¼ ounces, and connot see why bronze metal cannot be run out of a cupola successfully."

MONEL METAL PROPELLER FOUNDRY PRACTICE.

By C. T. R.

THE increased use of Monel metal for propellers has been very noticeable and its inherit properties make it remarkably adaptable for this work. Engineers early recognized that this "natural" alloy which consists of approximately 67 per cent. nickel, 27 per cent. copper, and 6 per cent. of other metals, principally iron and manganese, would find a large demand for propeller use provided it could be cast successfully. On account of the relatively scant knowledge of nickel and its peculiarities, considerable difficulty was experienced by foundries that first attempted to cast Monel metal propellers, but all obstacles seem to have been overcome by

the Bayonne Casting Co., Bayonne, N. J., who have successfully cast Monel metal propellers of 18,000 pounds each, and, in fact, have made castings of 25,000 pounds weight in one piece. It will, therefore, be interesting to note the foundry practice of the Bayonne Casting Co., according to information furnished by the Ruggles-Coles Engineering Co., of New York, who act as general sales agents for this company.

Practice of Casting Monel Metal.

The practice of casting Monel metal is very similar to that followed in many steel foundries. As the melting point is high, being about 2,500 degs. Fah., eight hours are required for heating. The melting plant consists of standard reverberatory furnaces which are oil fired, the fuel being fed by gravity and the melting being done by natural draft. The furnaces are charged with the metal in the form of pigs or slabs that weigh about 35 pounds each. No fluxes or alloys are necessary. At present the melting capacity of the plant is about 40,000 pounds daily, consisting of one furnace with a capacity of 30,000 pounds, another of 7,500 pounds, and a third of 2,500 pounds. Included in the shop equipment are also several Rockwell furnaces of 200 pounds capacity each.

In casting the large propellers, pits are used of 25 feet diameter and 5 feet deep. These are built in the form of submerged steel tanks with rolled plates. The adoption of this construction was due to the shifting nature of the ground on which the shop is located, and its proximity to tide water; further, the cost of construction was less than concrete. On the bottom of the base plate, an ordinary loam mold for the casting is built up. Millville gravel from New Jersey deposits is used, being the same grade of sand used by the steel foundries in the vicinity. The heat of the molten metal when poured exceeds that of steel and therefore an exceptionally good facing is required. The ramming of the mold is done by air rammers of the floor type and after the mold is in position and dried, the copes are bolted on to the base plate and a runner box with four apertures which feed directly into the mold is placed upon the copes and the head box inserted. The feeding is performed quickly from a 30,000-pound ladle into which the furnaces are tapped. This rapid pouring is necessary for the elimination of dross that otherwise might collect. The molten metal pours quite similarly to brass. The casting is allowed to set for four days in the mold before it is taken out. A 20-ton electric traveling crane with a 5-ton auxiliary commands the operations. There are also two 7½-ton jib cranes which serve for handling the metal in about one-third of the entire shop.

Monel Metal Propellers in Service.

Heretofore, propellers have been made largely of various kinds of bronze, particularly manganese bronze, but with the rapid development of the marine turbine the demand for a propeller metal that would stand even better the severe shock of high speed service, became manifest. Monel metal propellers have supplied this need and some of the largest fighting ships are equipped with them. The Argentine Republic's battleship "Rivadavia," claimed to be the largest and most powerful naval ship in the world, has three Monel metal propellers each of 16,000 pounds, and three similar ones have been cast for the same Republic's battleship "Moreno" now in construction at Camden. The U.S. battleship "Florida," is equipped with four 8,000 pounds each Monel metal propellers, while the "North Dakota" is fitted with two of 18,000 pounds each. Many torpedo boat destroyers of the U.S. navy are fitted with Monel metal propellers, most of them being of the three-bladed design, weighing about 2,000 pounds each.

It is interesting to note that a recent inspection of the U.S. battleship "North Dakota" in dry dock showed that the Monel metal propellers used suffered little effect of their long service. The bright silver polish of Monel metal propellers was well retained, and the enormous strength of the material prevents changes of pitch and the consequent losses of efficiency.

MONEL METAL PROPELLER FOUNDRY PRACTICE.

AUTOMATIC CAN MAKING MACHINERY.

WHEN it is considered that by far the vast majority of the food products which we consume come in tin cans, it is not difficult to realize that machinery for making these cans is a very important branch of manufacture.

Tin cans used for food products may be roughly divided into two main classes:—First, there is the soldered or packers' can, Fig. 11; and then there is the open top or so called "sanitary" can, Fig. 10. In the case of the packers' can, one of the ends has an opening which is somewhat smaller than the diameter of the can, and it is this opening which is closed by a soldered cap, after the goods are put inside. In this form of can, not only is the side seam soldered, but also the top and bottom are soldered to the body.

In the case of the open-top, or sanitary can, these are shipped with only the bottom in place and with the entire top separate. For these cans there is no small cap to be attached to the top, but the head of the can itself forms the cover. In the sanitary can, the top and bottom seams are folded over upon themselves or "double-seamed," and there is no solder used in the top and bottom seams. In order to make these unsoldered seams air-tight, a thin coating of a rubber-like substance is applied to the parts before they are put together and the tight rolling down of the double seam squeezes this material in the space between the sheets, entirely filling up the cracks and making them air-tight. While it is supposed that this form of seam makes a sanitary can, due to the absence of solder and the necessary application of acid in the soldering process; this is an exaggeration, for even in the sanitary can, the side or body seam is soldered, just as is the case with the ordinary packers' can.

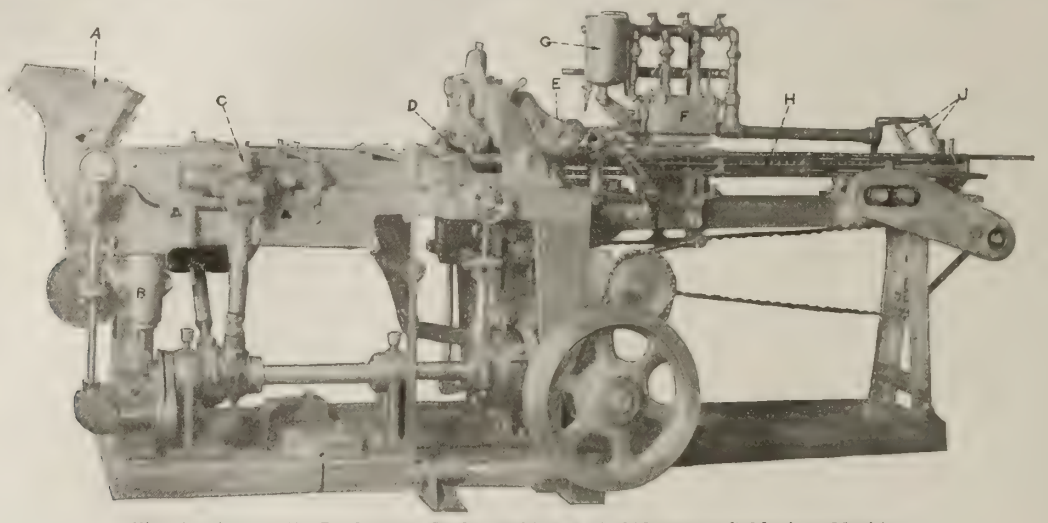

Fig. 1.—Automatic Lock-seam Body Making and Side-seam Soldering Machine.

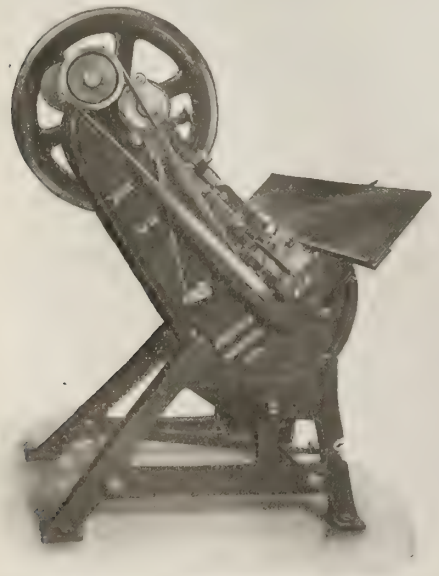

Fig. 2.—Press with Stagger Gauges and Tables.

Forming, Seaming and Soldering the Bodies.

Slitting the sheets of tin into strips which are afterward formed into can bodies is the first step in the manufacture. This slitting is done on a machine, carrying several rotary slitting cutters on an arbor. After the sheets have been cut to width and length, they are taken to the machine shown in Fig. 1. Here they are piled in the receiver A, and a suction arm is brought up, drawing away the bottom sheet by means of vacuum, produced by the vacuum pump B, also shown in Fig. 1. This sheet is next carried to the notcher at C. Here, when making bodies for the open-top or sanitary can, notches are cut from the corners of the sheet, the object of this notching being to remove the metal where it would be doubled over in too many thicknesses when the ends are double-seamed. For a packers' can whose end seams are not folded over, this notching is unnecessary, and this portion of the machine is omitted.

After this, the sheet passes on under the yoke shown at D, where a pair of arms rise up to curve the sheet around an arbor or horn. While being carried to the arbor the sheet is edged, that is, the two edges are hooked; one edge turned up and the other turned down, at a little more than a right angle; then, when the sheet has been wrapped around the arbor, the two hooks lock together. At this point wedges enter the arbor, causing it to expand and draw the metal tight, while the yoke at E comes down and presses the lock seam tightly together. This makes the seam in the side of the can body, which, however, is not air-tight, but has to be soldered.

Soldering is done after the arbor has released the can body, and it is carried along the conveyor H, passing first under an acid applier and then under the soldering iron below F. This consists of a piece of iron loosely supported inside of a frame having numerous Bun-

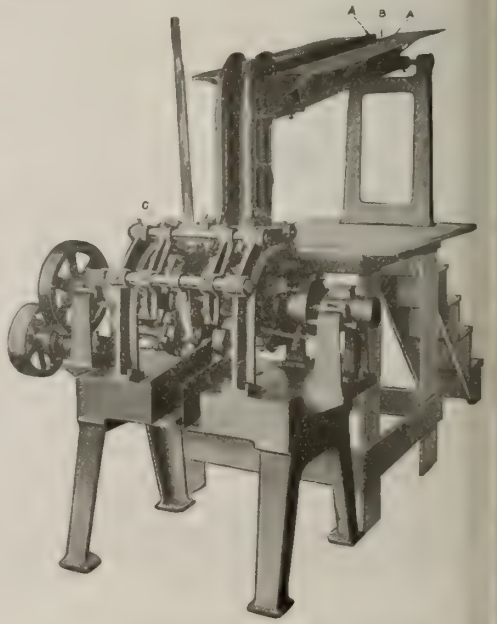

Fig. 3.—Automatic Round-can Header.

sen gas flames playing upon it. The iron thus being hot, a continuous piece of wire solder is fed against it and as the can bodies pass below it, this solder is transferred to the seam of the can, penetrating into the cracks between the sheets of tin, so as to make the seam

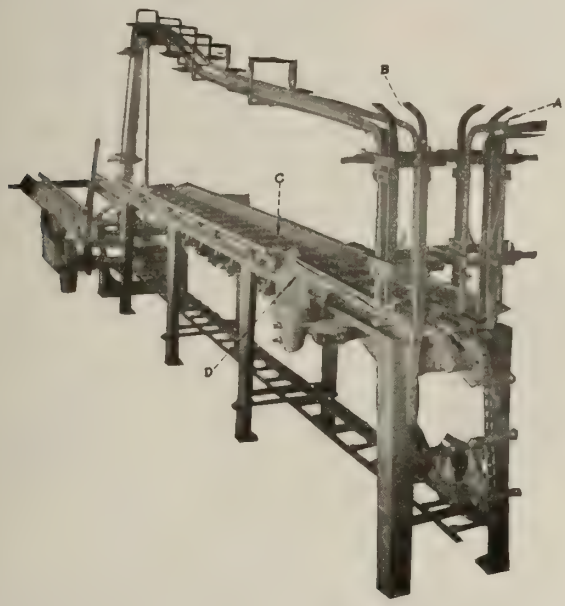

Fig. 4.—Automatic Floater or Head Soldering Machine.

tight and impervious to air. This done, the can body is carried further along the conveyor H and passes under the two solder wipers J, which wipe off any extra solder which may adhere to the top of the seam.

Stagger Feed Press.

In Fig. 2 is illustrated a press which stamps out can heads and at the same time presses them into the cupped shape which they must have in order to fit over the end of the can body. In this particular press, what is known as the "stagger feed" is applied, so that the round holes punched in the metal, being staggered, fit together much more neatly, making considerably less scrap than would be the case if the holes were not staggered. Also, a pair of shears, removes the flimsy scrap metal, to get it out of the way.

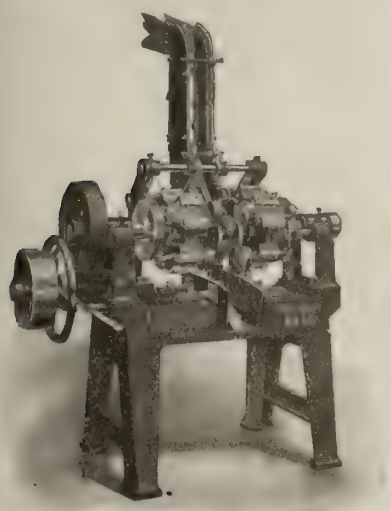

Fig. 5.—Automatic Round Can Flanger.

Heading Without Crimping.

When the can bodies and heads have been made, it is necessary to put these together. By the older methods, it was customary to make the head with a slightly flaring lip, so that it would fit easily over the end of the can and then it was necessary to mash or crimp this flaring edge down against the can body, to make it reasonably tight before soldering. With modern methods, however, the accuracy of the parts is such that it is possible to put the can heads directly onto the body, without any flaring and after-crimping. This is secured by feeding the heads into recessed dies, the shoulder of which guides the can body directly into the head.

In Fig. 3, one of the heading machines is illustrated and the bodies are fed into the trough at B, coming down through the centre of the machine, while the tops and bottoms are fed in through the narrow slots at A A. In the revolving part C, the head and bottom of the can are forced on over the body, there being numerous molds following around, one after the other, and pressing the heads and bottoms into place, so that a speed of 140 cans per minute is possible. These machines are also adjustable for various sizes, this one in particular being suitable for diameters of from 1½ in. to 4½ in. and lengths from 1¾ in. to 7 in.

Automatic Soldering.

As previously intimated, the next step after forcing the tops and bottoms upon the ordinary packers' can is to solder these tops and bottoms in place. This is done by the machine shown in Fig. 4, which is known as a floater. Observing this illustration, the trough C holds melted solder, kept hot by numerous gas flames beneath. The bottle D supplies a tray with acid which,

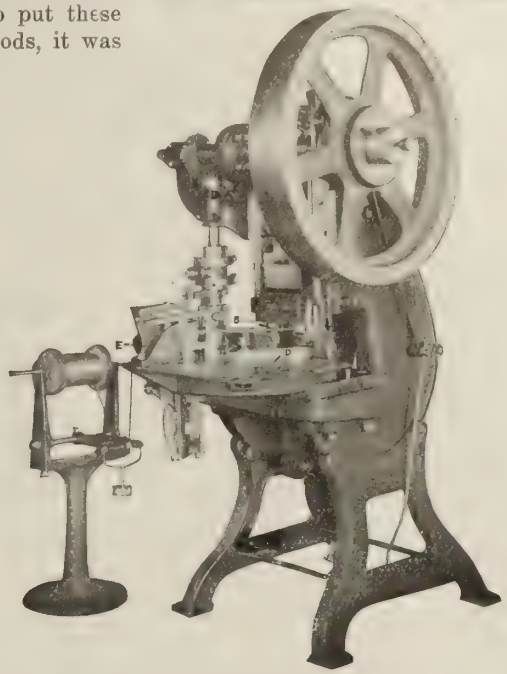

Fig. 7.—Solder Cap Hemming Machine.

of course, must first be applied to the parts. Cans coming from the header are fed into the conveyer at A, where they drop down to the tray and are rolled along on edge, slightly tipped up, so that one seam will dip and roll in the acid and then on to the tray C, where the can edge rolls along in a similar manner, in melted solder. The solder creeps up into the seam, following the acid and making an air-tight joint.

At the end of the solder tray the cans are dumped off, raised up in the conveyer shown above the machine, and brought back to the chute at B. From here they drop down and pass along the left-hand side of the conveyor, put-

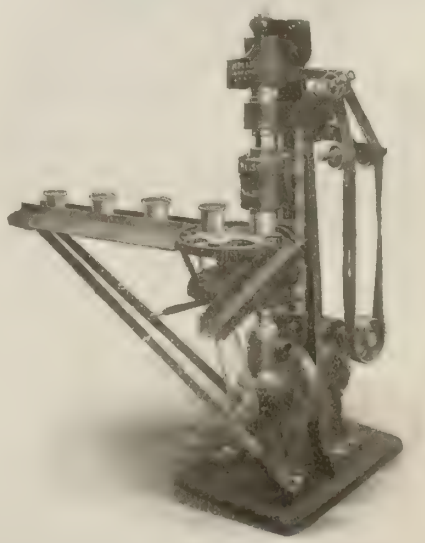

Fig. 6.—Automatic Stand-still Double Seamer.

ting the other end seam of the can, first in the acid and then in the solder, so as to seal this end as well. At the extreme end of the machine the cans are brought out upon the cooling belt, where the solder has time to harden. Provision may also be made for wiping off the excess solder. Such machines are built for a speed of 150 cans per minute and are adjustable to a wide range of sizes.

Double Seaming Sanitary Cans.

So far, we have been talking about packers' or solder-end-seam cans. To go back to the sanitary can, it will be remembered that the end seams in these are folded over on themselves or double seamed, there being no solder. The first step in obtaining this double seam is to put a flange all around the can by expanding the ends of the can body, that is, flaring the ends out at about a right angle. This operation is performed on the machine shown in Fig. 5, which is continuous in operation, takes a wide range of sizes, and flanges at the rate of about 140 or more bodies per minute. The bodies are fed down through the chute shown.

Before attaching to the bodies, the bottoms, which are stamped out by the press already shown, are passed through the compound applying machine shown in Fig. 9, this machine being used to apply the sealing compound. The tops or bottoms being fed into a dial are automatically carried into the machine, where by means of rolls the sealing compound is applied, after which they are discharged into a conveyer dryer (not shown). After passing through the dryer they are ready for the double seaming operation.

The can body, with bottom in place, is now placed on the conveyor of the

Fig. 8.—Automatic Can Tester.

machine shown in Fig. 6, known as the double seamer, and carried to the revolving dial, which automatically feeds it under the double seaming head. Four double seaming rolls are used. Each operation is accomplished by two rolls acting simultaneously at opposite points of the bottom, thus balancing the pressure and lessening the twisting tendency. During the double seaming the can stands still. After double seaming it is automatically carried away and deposited in a chute. This machine is also used for double seaming the tops on the filled cans.

Hemming the Solder Cans.

Fig. 7 represents what is probably the most interesting of all these can-making machines. This is known as the solder-cap hemming machine, and is

Fig. 10.—Sanitary Can.

Fig. 11.—Packers' Can.

used for applying solder to the edges of the small caps which are used to close up the final small opening in the top of a packer's can. In the illustration a large number of caps are shown on the table of the machine and they are fed to dies in a revolving dial plate, one die being visible at D and one on each side of it. Wire solder is fed from the reel and passes under the press A, where it is cut off and formed into a ring. It is then passed on by the revolution of the dial plate to the punches B and C, where it is flattened out, that is, the round wire is made into a flat rim, somewhat like a narrow gasket, and formed to fit the cap.

At D the operator places a cap, which is saucer shaped, on top of the solder ring and the two are then carried under the subpress E, where one edge of the thin, round sheet of solder is folded entirely over the edge of the cap and pressed down tight around the rim. No heat is applied, but the shape of the ring and the pressure hold it very rigidly in place on the edge of the cap. Beyond the subpress E, the dies automatically eject the caps with the solder in plate. These caps are shipped to the packer who, after the cans have been filled, solders the caps to the tops of the cans by other special soldering machines.

Automatic Tester.

One of the most important machines is shown in Fig. 8. This is the can tester and, as it name implies, its function is to discover the imperfect or leaky cans. The very minutest opening to air is sufficient to start fermentation in canned goods and the can manufacturer is forced to guarantee to the packer that not more than two cans per thousand shall show an air leak. With this limit of error it may readily be understood that careful inspection is necessary, even with the best of machinery.

Packers' cans are fed to this testing machine from a chute coming from the floater or soldering machine, and in the case of the sanitary cans, from the double-seamer. As the cans are received they are automatically gripped between the round plates carrying rubber gaskets, and as they are carried around and dipped into the water tank beneath, air at a pressure of from 15 to 20 pounds per square inch is applied through the center of the plates holding the cans in place. An operator at one side then carefully observes if any bubbles arise from the water, denoting a leak, and if one is discovered, the operator removes the leaky can. The other cans, which are perfect, are not disturbed by the operator but are carried up further and automatically dropped down to a chute to carry them off.

Driving of this machine is quite slow so as to prevent stirring up the water and forming bubbles from other causes than leaks. This slow speed necessitates the large number of can carriers, the particular machine illustrated having 30 and a capacity of 120 cans per minute. The air pressure is applied only to those cans which are under water. Another effort to eliminate disturbance in the water is to drive the machine by worm gearing, instead of spur, thus reducing vibration. It is said that with machines of this character, retests of all the cans passed through the machine in a day have repeatedly shown not a single leaking can among those passing out through the perfect chute during this time.

Fig. 9.—Compound Applying Machine.

Through the courtesy of the E. W. Bliss Company, of Brooklyn, N.Y., who are the manufacturers of these machines, we are enabled to reproduce the accompanying illustrations.

McCabe presents some of the choicest High-Grade Large Machine-shop Tools

TO BE FOUND ANYWHERE IN THE COUNTRY—Carrying a stock of Tools like this means the biggest kind of selling—and the prices must be low enough to ensure quick sales—

NILES 14-20 ft. Upright Boring and Turning Mill, 2 heads, Extension type, Motor Drive, with Motors complete, Modern Tool, in as excellent condition as the Boring Mills in some of the best Shops in this country.

Pond Machine Tool Co.'s 10 ft. Double-Head. Upright Boring and Turning Mill, Belt Driven.

Wm. Sellers Co.'s 7 ft. Upright Boring and Turning Mill, 2 heads, complete.

Other Boring Mills, Various Sizes to 2½ ft.

Wm. Sellers Co.'s 6 ft. x 6ft. x 25 ft. Iron Planer, with 4 heads, 2 on crossrail and one on each Housing.

Pond Machine Tool Co.'s 54 in. x 42 in. x 12 ft. Iron Planer with 3 heads, 2 on Crossrail.

Pond Machine Tool Co.'s 42 in. x 42 in. x 14 ft. Iron Planer with 2 heads, Extra Heavy; Weight, 26,000 lbs.

Niles Tool Works 36 in. x 36 in. x 26 ft. Iron Planer with 2 heads, Parallel Drive.

G. A. Gray Co.'s 36 in. x 36 in. x 12 ft. Iron Planer, 2 heads, Extra Heavy Pattern.

Planers of all sizes—Small as 16 in. in width.

Heavy Standard Pattern Triple-Geared Lathe—80 in. Swing, still in operation.

Niles Tool Works Heavy Driving Wheel Lathe—70 in. swing, Double Head.

Putnam Triple-Geared Lathe—70 in. Swing, 21 ft. bed—extra heavy.

Putnam Triple-Geared Lathe—56 in. Swing, 16 ft. bed.

Fitchburg Triple-Geared Lathe—54 in. Swing, 21 ft. bed—separate raising blocks also included.

Pond Triple-Geared Lathe—50 in. Swing, 32 ft. bed—extra heavy, Latest Pattern.

A $10,000 Planer

at less than half the new price—

is one out of about 175 different large size tools that you may select in the present J. J. McCabe stock.

An $8,000 Boring Mill

at three thousand dollars —

and these are modern up-to-date tools—in first-class condition.

Low Prices

urge you to investigate some of the big machinery buying opportunities at

"The greatest clearing house of them all."

Write for complete list.

Putnam Triple-Geared Lathe—48 in. Swing, 24 ft. bed with blocks to swing 66 in.—Extra heavy. Lathes—150 different sizes at least—from 14 in. swing up.

Niles Tool Works Heavy Double-Column Horizontal Boring, Drill- and Tapping Machine with Floor Plate—16 x 8ft., good as new.

Bement-Miles Co.'s 7 ft. Arm Half Universal Radial Drill with Swivel Head on Arm—Extra Heavy.

Western Co.'s 6 ft. Arm Full Universal Radial Drill—with Swivel Head and Swivel Arm—Weight 14,000 lbs.

Prentice Bros. Co.'s 5½ ft. Arm Plain Radial Drill—with table complete.

Bement-Miles Co.'s 5 ft. Arm Radial Drill — Full Universal — Extra Heavy—Weight 10,000 lbs.

Radial Drills, Plain and Universal—All sizes and styles.

Upright Drills also. 14 in. to 50 in. swing.

Baush Co.'s 14 Spindle Multiple Drill—Latest—High Speed.

Niles Co.'s Planer Type Milling Machine—34 x 11 ft.

Niles Co.'s Planer Type Milling Machine—34 x 9 ft.

Cincinnati Plain Milling Machine, Heavy Back-Geared, Table 60 x 14 in.

Gisholt Type Turret Lathe—24 in. —4½ in hole, 2 carriages, complete.

Other makes of Turret Lathes—all sizes.

Bement-Miles Co.'s Steam Hammer —4,000 lbs.—Double Frame.

Bement-Miles Co.'s Steam Hammer —2,500 lbs.—Double Frame.

Steam Hammers down to 700 lbs.

Bement-Miles 16 in. Stroke Slotting Machine—automatic feeds, complete.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

FOUNDRY AND MACHINE SHOP.

Bancroft, Ont.—Payne's machine shop and electric light plant were destroyed by fire recently.

New Westminster, B.C.—The New Westminster Foundry Company are erecting a $1,000 iron foundry here on Braid Street.

Hampton, N.B.—J. M. Logan's machine shop was destroyed by fire recently. The loss is only partly covered by insurance.

Owen Sound, Ont.—Fire damaged the plant of the Owen Sound Wire Fence Co. here to the extent of $20,000, covered by insurance.

Vancouver, B.C.—Col. Davidson, who was here recently, announced that Port Mann will be the site of an iron works, car shops, a working establishment and a dry dock.

Medicine Hat, Alta.—The civic industrial committee is in touch with a company which proposes to establish a steel works here.

Medicine Hat, Alta.—The Alberta Foundry & Machine Co. are enlarging their plant here, and expect to have the additions completed by the middle of March.

Meaford, Ont.—Toronto interests have secured the Corley farm and it is rumored that a new manufacturing company will establish a tile and sewer pipe plant here.

Vancouver, B.C.—Sir Donald Mann was here recently, and definitely announced that the C. N. R. would locate the principal repair shops of the company at Port Mann. He also confirmed the report that Port Mann is to become the location of extensive private industries, including a freight car building works.

Galt, Ont.—The big Goldie & McCulloch boiler shop, the largest in Ontario, has become too small and will be greatly added to. The new addition will be one-third the size of the present shop.

Brandon, Man.—Messrs. Thomas and Coutier, of this city, have secured the rights for Manitoba to manufacture the Only Elliot Belt Guide. A factory will be erected in the near future and machinery installed.

Port Colborne, Ont.—The Canadian Safety Appliance Co. have been registered and will establish a factory here. Electrical appliances of all kinds will be manufactured here.

Welland, Ont.—The Canadian Steel Foundries propose erecting a big blast furnace here to cost $1,500,000. Ground will be broken in the spring.

St. Thomas, Ont.—The Gasolectric Motors, Ltd., have decided to locate their head office here, and it is highly probable that the Canadian plant will also be established here. E. H. Thomas, of this city, is the president.

Montreal, Que.—A. C. Stead and James Hutchison, joint liquidators, of this city, are advertising the assets of the Parker Foundry Co., in liquidation. The plant consists of steel and grey iron equipment and appliances.

Cardston, Alta.—The Folsom Iron Works have made various improvements in their shops here recently. A new 10 h.p. gasoline engine was also installed.

Winnipeg, Man.—At a meeting of the shareholders of the Manitoba Bridge & Iron Works recently it was announced that an entirely new plant will be erected. Plans will be drawn for a plant said to be the largest in Canada, with the necessary accessories of foundries for steel and grey iron castings, machine shops, forge shops, etc. A new site will be acquired within a reasonable distance of Winnipeg.

North Bay, Ont.—It has been reported that the C. P. R. propose expending a large sum of money to erect repair shops and extensions here. The reported plans call for a six-track car repair shops 175x140 feet.

Norwood, Man.—The Winnipeg Steel Culvert & Granary Co. have taken out a permit for a new building, to cost $7,000, to replace the one destroyed by fire recently.

Kingston, Ont.—Plans involving an expenditure of $1,000,000 for the enlargement of the locomotive works here have been completed. Additional storeys are to be built to the present buildings and several new structures are to be started near William Street.

North Bay, Ont.—The town is asking the C. N. R. to guarantee shops or a divisional point, in return for certain valuable concessions here.

Kingston, Ont.—The Buffalo-Ontario Smelting Co. have secured a site and will establish a smelter here in the spring. The company's operations will be limited at first, but it is said that the ultimate expenditure will approximate $300,000.

Toronto, Ont.—Fire at the Queen City Foundry Co., at the foot of West Market Street, did damage to the extent of $2,200.

Merritton, Ont.—A branch factory of the Presto Light Co,, of Indianapolis, Ind., will be established here this spring. They will carry on the manufacture of automobile, carriage, boat, bicycle and other varieties of lamps. The initial expenditure will be $4,000.

Montreal, Que.—At a meeting of the Maisonneuve council recently a request was read from the Belgo-Canadian Co., asking exemption from taxation and other advantages in the event of their establishing a steel works in Maisonneuve. It was stated that the construction of their workshops involved an expenditure of $125,000.

St. John, N.B.—The Petrie Manufacturing Co., Hamilton, Ont., makers of the Maguet cream separators, have purchased a site here and will erect a warehouse and office to accommodate their Maritime trade.

Hamilton, Ont.—Schweier & Stephenson, machinists and engineers, have purchased Richard Quinn's machine shop, at 134 North Bay Street.

Victoria, B.C.—The Victoria Machinery Depot has made an arrangement with the Astoria Iron Works, of Astoria, Oregon, whereby all the can-filling machines patented by this firm ordered in British Columbia will be constructed at the Victoria Machinery Depot.

Sarnia, Ont.—Plans for the brass factory to be erected here by the Mueller Manufacturing Co., of Decatur, Ill., are well under way and construction will begin in the near future.

Hamilton, Ont.—It is rumored that the Union Drawn Steel Co. contemplate enlarging their plant here in the near future.

Calgary, Alta.—The Sawyer-Massey Co., of Winnipeg and Hamilton, propose erecting a warehouse here for the purpose of storing goods and making repairs.

New Westminster, B.C.—The Canadian Talbot Boiler Co. will establish a plant here to manufacture an improved marine and stationary boiler. The product is said to be indestructible—Cannot scale, pit or prime—occupies one-half the space of other standard tubular boilers, and weighs one-third. One of these boilers on exhibition here is a 25 h.p. and weighs 1,625 lbs. It has been tested to 2,000 lbs. pressure.

Winnipeg, Man.—The Excelsior Motor Works here suffered $75,000 loss by fire some time ago.

Sherbrooke, Que.—Three iron industries have been seeking loans from the municipality for the purpose of establishing and extending their plants here—the Jenckes Machine

DART
Dart Unions
These bronze faces can be quickly drawn together, whether the pipes are in or out of line, and form a connection that cannot leak, rust or corrode.
Made in all convenient types. Ask your jobber for them.

Cutting Crucible Costs

Cost and price are distinct terms.

DIXON'S CRUCIBLES

are less costly because of the service you get out of them. They give more heats and more general satisfaction than you usually get from crucibles.

WRITE FOR BOOKLET *No. 223-A.*

ALMOST all users will specify "Morrow" Studs, Set Screws, Cap Screws, Nuts where accuracy and absolute satisfaction are required.

MANUFACTURED AT INGERSOLL, ONTARIO.

Number eight Catalogue is now ready.

John Morrow Screw & Nut Co., Limited, Ingersoll

Co., the McKinnon Holmes Co., and the Canadian Rand Co.

Ingersoll, Ont.—The Motor Truck Co. are asking for a loan of $10,000 from the town to assist them in establishing a factory here. It is the intention of the company to have a plant and equipment within one year, valued at $20,000.

St. John, N.B.—Incorporation has been granted the Maritime Nail Co., head office in St. John. They are capitalized at $250,000. The incorporators are: S. E. Elkin, F. E. Marvin, E. C. Elkin, H. A. Marvin and C. P. Nixon, all of St. John.

New Westminster, B.C.—It has been reported from Coquitlam that the Schaake Machine Works, of this city, will be transferred there, if negotiations now under way are satisfactorily completed.

Weyburn, Sask.—The building now nearing completion and which will be used by Acton & Montgomery as a garage and machine shop, has been added to considerably, making room for additional business.

Cornwall, Ont.—There has been a movement on foot here to amalgamate the two foundries in Cornwall, De Rochie Bros, and J. Miller & Co. The joint stock company propose erecting a machine shop 50x100 feet and enlarging the foundry. They also contemplate adding a malleable iron plant.

Port Arthur, Ont.—It has been reported that the Rhodes-Currie Car Co. will establish a car plant between here and Fort William.

Galt, Ont.—The Canada Machinery Corporation, Ltd., has taken over the London Tool Works, of Hamilton. The corporation head office is located here.

Regina, Sask.—The Winnipeg Steel Granary & Culvert Co. are doubling the floor space of their factory here, and have also installed several more machines to enable them to keep pace with their increasing business.

Regina, Sask.—The Minneapolis Steel & Machinery Co. of Canada, have secured a warehouse here to look after the needs of the Prairie Provinces.

Vancouver, B.C.—The International Lead & Iron Co. will erect, this spring, in the vicinity of Spokane, a plant for the manufacture of pig iron and cast iron pipe.

Belleville, Ont.—The United Motor Car Co., which will manufacture automobiles in Canada to use the Augustine rotary engine, propose establishing a plant here to cost approximately $175,000.

Medicine Hat, Alta.—The Alberta Rolling Mills are adding a 50x100 shipping warehouse to their present plant here. A number of additional rollers will also be added in the near future.

Moose Jaw, Sask.—The Rumley Co., one of the largest manufacturers of threshing machinery, have decided to locate here, and will erect a warehouse early this spring.

Wingham, Ont.—The Western Foundry Co. have decided to instal a central power plant and generate their own electricity to operate both their immense plants, which will occupy ten acres of land.

Owen Sound, Ont.—The ratepayers will vote on two industrial by-laws on March 9, one to expend $1,500,000 for a shipbuilding and dry docking plant.

MUNICIPAL.

Moose Jaw, Sask.—The city council is advertising for tenders for an elevated water tank. It will have a capacity of 75,000 gallons.

Vancouver, B. C.—The ratepayers have authorized the following expenditures: Sewers and permanent improvements, D. L. 301, $90,000; acquisition of paving plant, $100,000; Seymour waterworks extensions, $350,000; and general waterworks extensions, $275,000.

North Vancouver, B.C.—The ratepayers passed the following by-laws: Waterworks loan, $125,000; Rice lake reservoir, $75,000.

Edmonton, Alta.—The city proposes spending the following amounts: Street railway, $602,006.67; water filters, $29,686.66; waterworks building, $9,733.33; city warehouse and workshop, $5,353.34.

Vernon, B.C.—The city council passed a by-law to provide $12,000 for sewerage extensions.

Victoria, B.C.—The citizens approved the letting of a contract to bring in a new water supply from Sooke Lake. This involves an expenditure of approximately $1,200,000.

Toronto, Ont.—The city will ask the Ontario Legislature for authority to issue debentures without a vote of the people to the amount of $100,000 to cover the expenses in connection with repairs and extension of the intake pipe.

Biggar, Sask.—The municipality is taking steps to borrow $9,000 for road grading, tools and machinery.

Ormstown, Ont.—A by-law providing for sewerage and waterworks is being prepared for the ratepayers.

Edmonton, Alta.—The city is taking steps to instal a municipal gas plant.

Burnaby, B.C.—The ratepayers have carried the by-law providing $250,000 for a waterworks system.

THE SHIRT SLEEVE MAN

is the one to appreciate the points of Drummond Lathes.

They are designed, built and priced for the small man, the man with limited capital, who, none the less, must have accurate and well-made tools.

In England the lathe illustrated here is called "The Workman's Lathe" and it sells to garage owners up and down the country.

It is a husky, *good* tool and its price is kept low by its lacking appearance, finish, etc., and in no other way.

SPECIFICATION

Height of centres,	6 in. to 9 in.
Length of bed,	4 ft., 6 in.

LET US FIGURE ON YOUR REQUIREMENTS
GALT FOUNDRY CO, GALT, ONT.

Victoria, B.C.—The ratepayers have authorized an expenditure of $200,000 for the waterworks and $450,000 for sewers.

London, Ont.—The city is applying to the Legislature for power to borrow the following amounts: $5,000 for a weigh scales and public convenience; $50,000 for an incinerator and plant, and $57,000 for extending the waterworks system.

Sarnia, Ont.—It is proposed to remove the Sarnia waterworks to the lake shore.

St. Thomas, Ont.—The council has been discussing the proposal to renovate the local street railway system. The report of the experts regarding the municipal heating plans are also being considered. By-laws covering these improvements will likely be submitted to the ratepayers in the near future.

Parry Sound, Ont.—The ratepayers carried the Standard Chemical, Iron and Lumber Co. by-law by a substantial majority. It calls for a bonus of $25,000 by way of loan.

Kamloops, B.C.—The ratepayers have authorized an expenditure of $60,000 for an auxiliary steam plant and a new reservoir.

Stettler, Alta.—Stettler proposes to expend $1,107,280 for the purpose of establishing a sewerage system.

Calgary, Alta.—Steps are being taken to prepare plans for a sewerage disposal plant here.

Port Stanley, Ont.—The Port proposes to expend $22,000 for a waterworks system.

ELECTRICAL.

Calgary, Alta.—The city proposes to expend $368,000 extending the light and power system.

Barrie, Ont.—The town will seek power to issue $80,000 debentures to construct a pole line to the Simcoe Power Company's plant.

Edmonton, Alta.—The city will expend $200,000 for power plant improvements, and $275,000 for telephone extensions.

Toronto, Ont.—The city has applied for power to authorize an expenditure of $2,200,000 to equip an electric power plant.

Orillia, Ont.—The town will apply to the Legislature for power to borrow $80,000 for power purposes.

London, Ont.—The city will apply to the Legislature for power to raise $90,000 for electric light extensions.

Edmonton, Alta.—The city proposes to expend $62,780 for lighting purposes.

Kamloops, B.C.—The ratepayers defeated the $300,000 hydro-electric by-law.

GENERAL MANUFACTURING.

Windsor, Ont.—The Frederick K. Stearns & Co. have decided to erect a $25,000 addition to their plant here. Plans are in the hands of Crane & Pennington, architects, of this city.

Thorold, Ont.—James Battle is promoting a company which proposes to establish a $1,000,000 paper plant here. The new industry will employ about 150 men.

Highgate, Ont.—The British-Canadian Canners have decided to erect a big cannery here, at a cost of $45,000.

Woodstock, Ont.—The Sanitary Manufacturing Co. have been incorporated and will locate a factory here. They will manufacture filters, refrigerators, woodenware, furniture, carpet sweepers, vacuum cleaners, etc.

Halifax, N.S.—The Nova Scotia Knitting Co., of Eureka, N.S., has passed into the hands of J. C. McIntosh & Co., of Halifax. The plant will be enlarged with $25,000 worth of new knitting machinery.

Niagara Falls, Ont.—The Sanitary Packing Co., of Toronto, is erecting a large factory half way between Queenstown and Niagara-on-the-Lake.

Souris, Man.—The business of the Arnett Furniture, Ltd., has ben sold to a new company, who will make a specialty of office and store fixtures.

Galt, Ont.—A number of local capitalists will establish a brick industry here to use the Berg process. A $40,000 plant will be erected. W. B. Shaw is the superintendent.

New Toronto, Ont.—The T. N. Firth & Sons Co. will establish a large factory here. Building operations will commence in the near future.

Portage la Prairie, Man.—The pump factory here, owned by H. J. Hughes, was badly gutted by fire recently. The woodworking machinery was badly damaged.

St. John, N.B.—The Royal Block Powder Co., of Portland (Me.), have definitely decided to erect a blockite factory here. They will build seven buildings, each 60x40 feet by 30 feet high. Construction will begin this spring.

Blairmore, Alta.—The Keystone Portland Cement Co. will establish a big industry here and have purchased the Frank Smelter and the Blairmore brick plant. The machinery of the new plant will be driven by individual motors.

Wallaceburg, Ont.—The Dominion Carlite Explosive Co.'s plant was destroyed by fire recently.

Moose Jaw, Sask.—The Robin Hood Flour Mills have decided to re-build in this city. A flour mill of concrete and a separate breakfast food mill, with elevators and modern power house, will be erected as soon as possible.

Vancouver, B.C.—F. A. Bean, of the International Milling Co., owning mills in Minnesota, Iowa and Moose Jaw, visited Port Mann recently and selected a site for terminal ele-

vators, and a 5,000-barrel flour mill. Construction will start in 1913.

Brantford, Ont.—The plant of of the Brantford Roofing Co. will be greatly enlarged this year.

Niagara Falls, Ont.—The Urschel Bates Valve Bag Co., of Toledo, Ohio, will establish a branch factory here at once. It will give employment to 75 men.

Windsor, Ont.—The city is to have a new industry to be known as the Canadian Gas Co., capitalized at $1,000,000.

St. John, N.B.—The Consolidated Pulp & Paper Co., capitalized at $5,000,000, will erect a big paper mill here. They have taken over the Gibson lumber properties, at a cost of $2,000,000. The new mill will be located near the pulp mill at Fairville.

Lethbridge, Alta.—The Canadian Swift Co. will establish a $75,000 plant here. A warehouse, cold storage plant, and general wholesale headquarters will be built.

Medicine Hat, Alta.—Mr. MacIntyre is promoting a company to manufacture porcelain ware of every description, dishes, jugs, etc. They propose to locate a $40,000 plant here.

Saskatoon, Sask.—The Saskatchewan Manufacturers & Contractors, Ltd., propose erecting a factory here. They will manufacture an exclusive line of fireproof building material.

Moose Jaw, Sask.—The Western Manufacturing Co. will establish here the largest and best equipped woodworking factory in the Prairie Provinces.

Dartmouth, N.S.—The Nova Scotia Carriage Co., now operating in Kentville, N.S., propose establishing in this place. They propose installing $50,000 worth of modern machinery.

Lethbridge, Alta.—The Martin Trunk Co., of Picton, Ont., propose establishing a $40,000 trunk factory here.

Ottawa, Ont.—The British American Bank Note Co. will erect a $75,000 building here. The plans have been approved.

BUILDING NOTES.

Vancouver, B.C.—Sullivan & Considine, of the Orpheum theatre, will erect a ten-storey office block here to front the theatre. The improvements will represent an expenditure of $350,000.

Saskatoon, Sask.—David Webster, architect, has prepared plans for a $75,000 office building here.

Vancouver, B.C.—A syndicate, headed by J. Coughlan & Son, propose erecting a $600,000 building here. It will be eighteen storeys high.

Toronto, Ont.—It is rumored that Sir Rodolphe Forget contemplates establishing a fifteen-storey building here at the corner of King and Yonge. The project has not yet been confirmed.

Vancouver, B.C.—The British Columbia Auxiliary Canadian Bible Society will erect a $112,000 ten-storey building here.

Vancouver, B.C.—Another ten-storey building, to be known as the Grossman building, will be erected here, at a cost of $500,000. It is being financed by Abram Grossman.

Toronto, Ont.—Plans have been prepared for the new Technical School, which will cost approximately $900,000. It will be the best equipped in the world.

Montreal, Que.—J. O. Gravel has taken out a permit for a ten-storey building, to cost $136,000. It will be erected at the corner of Notre Dame and St. Sulpice Streets.

Port Arthur, Ont.—The supplementary estimates brought down in the Federal House contain an appropriation of $65,000 for an armory and drill hall here, and a like amount for Fort William.

Vancouver, B.C.—Henry Birks & Sons will erect a ten-storey store and office building here next summer. The total cost will be $200,000.

TRADE NOTES.

The H. W. Johns-Manville Company, already well known in the lighting field by reason of their J.-M. Linolite System of Illumination, have acquired the sole selling agency for the entire products of I. P. Frink. An engineering department will be maintained along very extensive lines. This department will maintain a corps of engineers throughout the United States and Canada, and be equipped to place data and recommendations in the hands of all interested in any subject pertaining to illumination.

Schumacher & Boye, Cincinnati, manufacturers of engine lathes, have been succeeded by the Boye & Emmes Machine Tool Co. The change was brought about by Mr. Boye and Mr. Emmes purchasing the interest of Mr. E. A. Schumacher in the firm of Schumacher & Boye. Mr. Emmes has been with the old firm for about fourteen years and had full charge of the shops during that period. He is well and favorably known to the trade.

The Vulcan Engineering Sales Company has been organized and incorporated with offices in the Fisher Building, Chicago, and 30 Church street, New York. The company controls the entire product and will handle all sales of

the Hanna Engineering Works of Chicago, Mumford Molding Machine Company, of Plainfield, N.J., and O. M. S. Company, of New York. Further factory arrangements are under way and the Vulcan Company will own and manufacture a number of railway special tools and equipment for shop and maintenance departments. The officers are: H. K. Gilbert, President, formerly vice-president of the Buda Company, and P. W. Gates, Secretary and Treasurer, now President of Hanna Engineering Works, formerly president of Gates Iron Works. E. H. Mumford, now Vice-President and General Manager of Mumford Molding Machine Company, will continue in the same position and duties as heretofore and William L. Laib, Vice-President and Secretary of the Hanna Engineering Works, will continue in his present position with that company.

Robey & Company, Ltd., Lincoln, England, Manufacturers of high speed enclosed engines, air compressors, mining, stone crushing and coal conveying machinery, are putting their lines on the Canadian market. Their Canadian business will be in the hands of Mr. Alf. J. Jones, A.M.I. Mech. E., an engineer of wide experience and practical knowledge. Mr. Jones will also handle electrical machinery manufactured by Crompton & Co., Ltd.; wood working machinery of Roscam & Co., Ltd., as well as the paraffin heavy fuel and speed engines made by Chas. Price & Son.

The Engineers' Representative Co., with offices at 201 Board of Trade Building, has been formed just recently. The manager is Robt. Holmes and the sales manager P. O. G. Janes. This firm will act as agents for firms having engineering, machine shop and power house supplies and equipment of all kinds. Both men are practically and technically trained engineers of wide experience and will no doubt be in a position to handle successfully any work which they may undertake. The agencies they will carry are not yet decided upon, but they are in negotiation with several first-class firms.

A. H. Winter Joyner, Ltd., 76 Bay St., Toronto, report having had a good year in 1911, and state that the prospects for 1912 are excellent. They hold the sole Canadian agency for the Helios Mfg. Co., Philadelphia, Pa., and have recently completed an installation of the latter company's flame arc lamps (25 cycle) at the Western Cattle Market, Toronto, where they are giving excellent satisfaction. The firm are also representatives for the Pemco street lighting fixtures and at present have a contract on hand for installing the same at Berlin, Ont. Other firms represented by the A. H. Winter Joyner, Ltd., are the Western Electric Instrument Co., Newark, N.J., whose instruments the Toronto Hydro-Electric use exclusively, and the Bristol Co., Waterbury, Conn., the well-known makers of pyrometers and recording instruments of all kinds.

FOUNDRY AND MACHINE SHOPS.

Galt, Ont.—Sheldons, Ltd., will build next summer an entirely new foundry covering an area of 110x200 feet. Two cupolas will be installed and also electric cranes. The company will also extend their machine shop up to the limits of their present property.

BOOK REVIEWS.

An interesting and valuable contribution to the ball bearing literature of the present year is the Engineering Edition of catalog-treatise, issued by The New Departure Mfg. Co., of Bristol, Conn. This is fresh from the press, contains seventy-six (76) pages, and has been prepared by the company's staff of ball bearing specialists and engineers. It gives valuable information of a technical character, and is fully illustrated by fine engravings. Typographically the book is a product of the American Lithograph Co., of New York city, and creditably reflects the skill of that house in modern high grade catalogue work. The New Departure Mfg. Co. offer to send this catalogue on request to manufacturers, purchasing agents, designing and mechanical engineers, and other responsible persons who are interested. We suggest that such requests be made on the letter head of the firm with which they are connected. Address The New Departure Mfg. Co., Bristol, Conn.

CATALOGUES RECEIVED.

The Cleveland Twist Drill Co. have issued an attractive little folder calling attention to the recent extraordinary feat performed by a 1¼-inch "Paragon" high speed drill in drilling through cast iron at the rate of 57½ inches per minute. The folder is artistically printed in colors, the inside showing reproductions of the leading technical papers which published particulars of the above performance. Amongst these, Canadian Machinery occupies a prominent position.

National Cutters

MR. BUSINESS MAN, ARE YOU PROGRESsive? It's up to you to test "Consolidated," our new process carbon paper. Because it costs less. Soft finish, without smutting, and clear, permanent copies. Write for sample sheets and prices. "Consolidated," Stratford, Ont.

FROM NOW TILL THE END OF THE YEAR we offer unusually good bargains in second-hand typewriters. They are carefully rebuilt, work and look like new, but the price is a mere fraction of the original cost. Write for catalogue. The Monarch Typewriter Co., Ltd., 46 Adelaide St. West, Toronto, Ont.

WAREHOUSE AND FACTORY HEATING systems. Taylor-Forbes Company, Limited. Supplied by the trade throughout Canada (tf)

These are the telling points about

Bakelite

Valve Discs

THEY will not leak under high temperature, excessive pressure or when used in acids or other special liquids. Neither cold water, dry or superheated steam has the least effect upon them. BAKELITE Discs are a gas-tight fit

BAKELITE is a successful substitute for expensive metal. Its structure is fibrous, giving strength and hardness. It can be reground and refaced, always retaining a uniform surface. It cannot be injured except by accident or friction.

Remember Bakelite PUMP VALVES do not warp with changes of temperature.

Order your valves fitted with Bakelite Valve Discs and stop that perpetual annoyance and expense caused by leaking valves. Depend upon it, Bakelite Valve Discs will not leak.

Write for prices or ask your dealer.

PLASTICS, Limited

METHOD OF WELDING STEEL CASTINGS

One Dollar's Worth of Laffitte Welding Plates

saved $240.00 worth of steel castings.

Stop throwing your profits in the scrap pile. There are hundreds of cracked, broken or imperfect castings scrapped. You can reclaim them by the use of LAFFITTE Welding Plates and save hundreds of dollars.

The LAFFITTE Welding Plate makes a perfect weld in one-third the time, fuel and labor. There is no change in method and no special equipment necessary.

LAFFITTE Welding Plates homogeneously weld anything of iron or steel---from Norway iron to high carbon tool steel.

Samples free on request.

MORE AIR

FOR THE MONEY

The class "NE-1" compressor delivers more air for the money invested and the power consumed, month after month, than any small compressor heretofore offered. It should, however, it's manufactured to be a leader. It embodies all the modern ideas in air compression.

The "NE-1" is obviously an aristocrat. When you consider its construction: the large, amply oiled bearings, the perfectly balanced rotating and reciprocating parts; the large, free air ports; the high grade workmanship and many other features which it embodies, and which are detailed in our Pamphlet K-92, you will agree with us that it is a superior little machine.

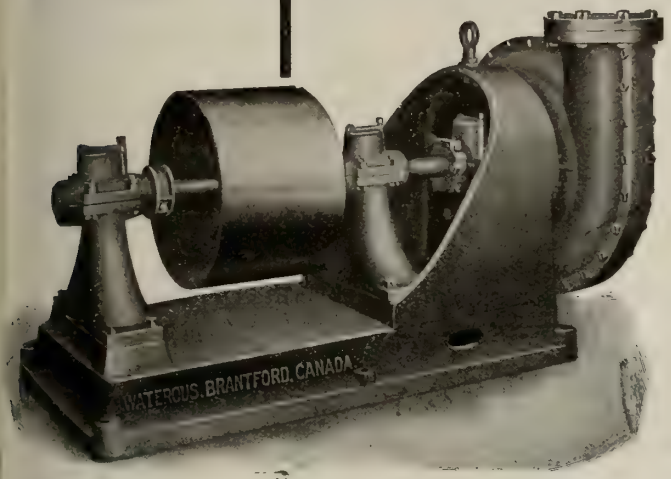
NOTICE
THE
SPLIT-BASE
IT'S NEW

THE WATEROUS SPLIT-BASE PUMP



The Waterous Horizontal Pump shown herewith is the type most extensively used for all purposes, and for general work is the best pump on the market. It is exceptionally strong and solid.

The pump has few parts to get out of order. It is put together to stay right and it does. The runner is of large diameter, of special wear proof material and runs comparatively slowly. The exceptionally heavy shaft is carried in a long bearing, lined with the best babbitt metal. The pulley is large, turned all over and perfectly balanced. The hub bearing is long, carries the runner without end play, and is furnished with a **split** bronze packing gland.

The split-base is its special feature, permits the removal of the operating parts without disturbing pump foundation.

The pump is built in sizes up to 14 inch discharge opening. Pumps are always kept in stock and can be shipped immediately. For further information and general dimensions—

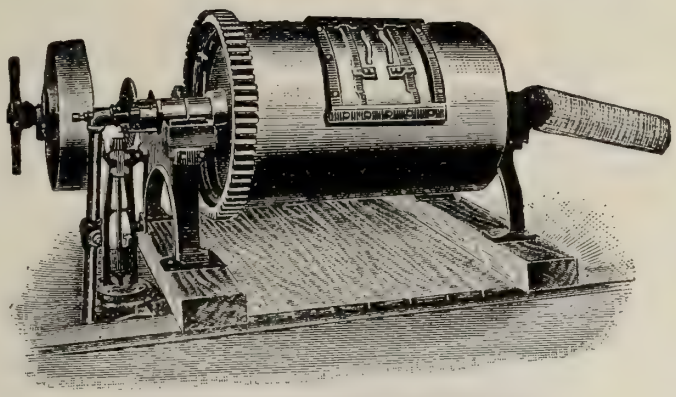
A GOLD MINE

SAVE YOUR IRON



SLY'S PATENT IRON CINDER MILL

Patented, No. 514097. Patented, No. 841728.

may be at your disposal on your very premises. Look out of your side window or back door and see if you have not an accumulation of cupola dump, and other foundry refuse, which is a total loss to you in its present state. Why not add to your profits and install one of the Sly Patent Cinder Mills to reclaim this iron and be astonished at your former loss and pocket the rich returns from your newly-discovered mine.

Sly's Patent Iron Cinder Mill will save 95% of the iron contained in your cupola dump and gangway scrapings and 75% of the coke. Iron is valuable, then why throw it in the dump? Iron recovered by this Mill is better than machinery scrap. Study economy in a foundry and your profits will increase accordingly. Mill will pay for itself three or four times every year, and we have records of Mill paying for itself twelve times a year. Let us know amount of your daily melt and we will quote. *Write for Cinder Mill Catalogue F.*

We also manufacture Cleaning Mills, Dust Arresters, Sand Blast and Foundry Equipment.

THE W. W. SLY MFG. CO., CLEVELAND, O.

The Making of Hollow Castings

The recent introduction of King Kore Kompound has now rendered this, once somewhat difficult, part of Foundry practice comparatively easy.

It has, also, reduced the core expense by more than one-half.

This compound is a black, dry powder, and is used as flour is used, but with one-half the quantity is produced greater and better results.

Its use avoids the danger of swelling or "blowing." The core easily comes out of the casting, and when old cores are ground up, in the rattler, or otherwise, the sand so made is used over again.

The core compound it contains, again becomes a binder under heat of the core oven, as it melts, and so it is used over and over again.

This is Foundry Economy; Flour, Rosin, etc., are now luxuries.

A barrel of King Kore Kompound will be sent "subject to approval" to any inquiring mind.

That is the Stevens' System of trying before buying.

I have copies of proportions of compound to sand used and methods followed in core rooms of Foundries in thirteen different States. This information, with other printed matter relative to the subject, will be mailed on request.

I maintain a direct branch at 137 Jarvis St., Mr. J. M. Mayers, Manager, Toronto, Ont., where is stocked a supply of Foundry Facings, Foundry Supplies, Buffing Compositions, of my own manufacture.

The stamp of quality pervades them all.

TWIST DRILLS, REAMERS, CHUCKS, CUTTERS, TAPS, DIES, ETC.

Morse Twist Drill & Machine Co.

NEW BEDFORD, MASS.

Think Deeply—The More You Think, The More You Will Be Impressed

"Sisco Acorn Steel"

Is Sweden's Best Product FOR ROCK DRILLS

Tests have proved this steel has less tendency to crystallize and break than the best steels used for this purpose.

This steel has the right amount of carbon and at the same time is tough, because it has body. Does this not mean holding a better cutting edge, thus saving the time and labor of frequent sharpening?

Being a steel made on a Charcoal furnace, it is able to stand abuse of treatment without losing efficiency.

What does it mean? Increased footage and what else? Just think.

Write for our Guarantee.

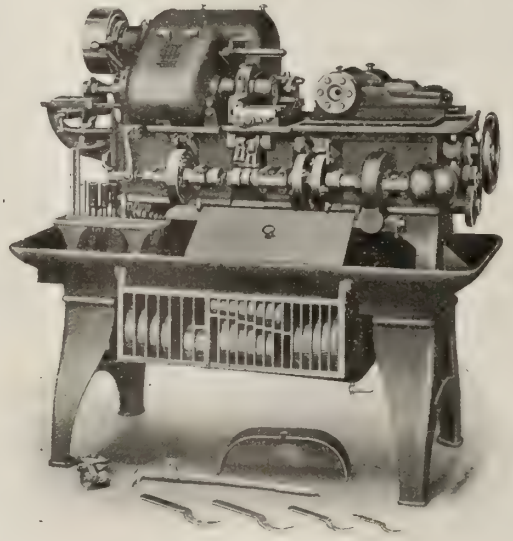
SWEDISH IRON & STEEL CORPORATION — SISCO — NEW YORK-NEW ORLEANS

SWEDISH IRON AND STEEL CORPORATION

12 Platt St., NEW YORK, N.Y. 428 Race St., NEW ORLEANS, LA.

Canadian Distributors: Lammers & Carleson, Montreal.

B. & S. Automatic Screw Machines Insure Both Accuracy and Rapid Production



No. 2G Automatic Screw Machine.

There are two classes of screw machine work. In one, production is of more importance than accuracy; in the other, accuracy is the first requirement. B. & S. machines are not only adapted to both classes, but are also capable of producing very accurate work at exceedingly fast rates. Such a combination of accuracy and productive capacity is well worth investigating.

We make a complete line of these machines, suitable for all classes of work, from watch parts and dental findings to the smaller parts of heavy machinery, automobiles, etc.

Write for Our General Catalogue.

Brown & Sharpe Mfg. Co., Providence, R.I., U.S.A.

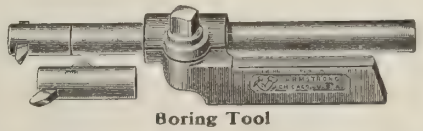
WISE PEOPLE TELL US

Nine out of every Ten Pounds of High Priced Tool Steel used in Forged Lathe and Planer Tools is absolutely wasted and that ARMSTRONG TOOL HOLDERS save Nine Dollars out of Ten they used to pay for Tool Steel, besides saving ALL FORGING and nearly all Grinding, while giving them Tools which do more and better work—Are YOU still forging Tools ?

Turning Tool

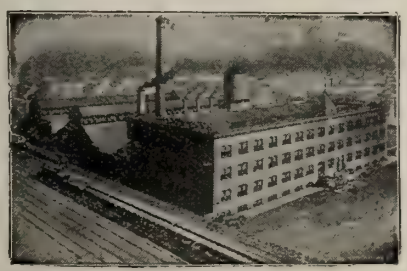


Boring Tool

Planer Tool

NOTE EXTRA LARGE TOOL STEEL SET SCREW AND REINFORCED SUPPORT UNDER THE CUTTER.

THEY GIVE INCREASED CAPACITY AND LASTING QUALITY



Do you want our Catalog ?

"W & B" Wrenches Stand the Pull and Strain

All wrenches may look alike. But there is a difference. Just those fine points may be lacking necessary to make it the perfect tool.

YOU WILL SAVE BY USING "W & B" WRENCHES

They mean saving in freight when you can order all your Wrenches from one manufacturer.

They mean quality with a guarantee and a trade-mark backed by a Company with 58 years' manufacturing experience.

WHY HANG

to precedent and buy the same Wrenches because you have always done so?

IT IS TIME

that you learn what "W & B" Wrenches will accomplish for you.

IT DOES NOT PAY

to make expenditures for poor wrenches. You should consider

THE RECORD, REPUTATION

ability to produce, careful attention to manufacturing detail, and the character of the materials.

GIVE "W & B" WRENCHES A TRIAL AND TEST THEM

in competition with Screw and Drop Forged Wrenches of other makes. You will then realize that you have adopted Wrenches that:

1. ARE MADE OF ABSOLUTELY PERFECT MATERIAL.
2. ARE CORRECTLY DROP FORGED, MILLED AND FINISHED BY EXPERT MECHANICS.
3. ARE CAREFULLY INSPECTED.
4. WILL MOVE THE STIFFEST NUT WITHOUT BREAKING.
5. SAVE THE COST OF RENEWALS.
6. ARE THE STANDARD OF QUALITY.

The same breaking strain test will convince you of their superiority, then avail yourself of the best Wrench quality and service.

WRITE US ABOUT YOUR WRENCH REQUIREMENTS.

HIGH GRADE TOOL STEELS

FROM STOCK OR IMPORT

J. Beardshaw & Sons, Ltd. BALTIC STEEL WORKS SHEFFIELD

"SINGLE CONQUEROR," for Chisels, Cold Sets, Mining and general use.

"DOUBLE CONQUEROR," suitable for Benches, Taps, Dies, Snaps, Shear Blades, etc.

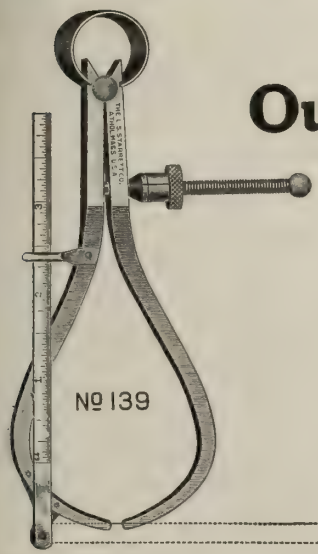
"CONQUEROR" High-Speed Steels in Rounds, Squares, Flats, also Profile Sections. Also High-Speed Drills of which I carry a large assortment.

PRICES RIGHT AND QUALITY GUARANTEED SATISFACTORY.

ALEXANDER GIBB

13 St. John Street -- -- MONTREAL

Our Profiles



N E W
Outside Spring Calipers with Patent Rule Attachment

It is so made that zero will always come in line with one caliper point—there is only one easy reading to make.

When folded back out of use the rule is held by a snap-catch.

5-inch Fay No. 75 outside calipers with quick adjusting spring-nut—4-inch rule graduated in 32nds and 64th. Send for descriptive folder No. 139. Price $2.25.

This is one of the many fine tools we make. Get the Starrett 274-page catalogue. There is much information in it, which will be useful to you.

Send for Catalog 193.

Cyclone Hoists

are simple and efficient. All bearings are graphite bronze, self lubricating, and require no oil.

They have 80 per cent. efficiency and are of ½ to 20 tons capacity. We stock from ½ to 5 tons, but can supply greater capacity at short notice.

Matchless Trolleys

will pick up and move any load and place it just where you want it. They are adjustable to any size "I" beams.

We also carry Gravity Molding Machines, Jar and Squeeze Molding Machines, Hauck Oil Burners, Acme Parting, Red Facing.

A post card will bring you our catalogue. Send for it to-day.

Books for Foundrymen

Three good Books that should interest Foundrymen who wish to know more about their work.

PATTERN MAKING. By James Ritchey, Instructor in Wood Working, Armour Institute of Technology. 160 pp., 250 illus. Cloth binding. Shows the reader how to take the blueprint and from it make the pattern for any kind of casting under any condition. The allowances for shrinkage, draft, and finish are explained. Simple and built-up patterns of all kinds are clearly treated. Various special cases are taken up, such as pulleys, cranks, pipe connections, valves, etc. Price $1.00

FOUNDRY WORK. By Wm. C. Stimpson, Head Instructor in Foundry Work and Forging, Department of Science and Technology, Pratt Institute. 160 pp., 150 illus. Cloth binding. A practical guide to modern methods of molding and casting in iron, brass, bronze, steel and other metals, from simple and complex patterns, including many valuable hints on shop management and equipment, useful tables, etc. Price, ... $1.00

PATTERN MAKING. By G. H. Willard. To which are added chapters on Coremaking and Molding. 214 pp., 312 illustrations. Cloth binding Dealing with the practical experience of foundry work, tools required; woods adapted for the work; turning; and all kinds of patterns. Price, postpaid .. $1.00

MACLEAN PUBLISHING CO.
143-149 University Ave., - - TORONTO

SLOCOMB ACCURACY

The careful attention given to details in making all our tools is making the Slocomb accuracy something worth having.

Isn't it worth something to you to **know** that you are getting a tool that is right, than to just think it is.

We are specialists in the tools we make, and every one is guaranteed.

If you haven't used our tools, it's time now that you did, and we know that you would continue doing so.

Send for our new Catalog, No. 13C.

Center Drills

Made of SEMI HIGH SPEED STEEL

Can be bought a dozen of a size in a box, or a case and eight sizes of drills, as shown in cut below.

J. T. Slocomb Co.

Providence, R.I., U.S.A.

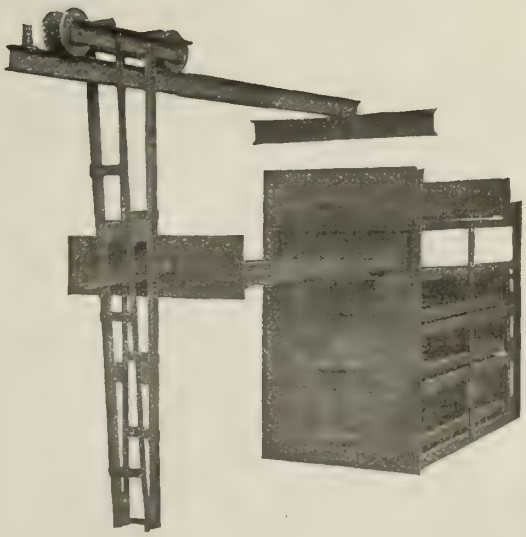
PROMPT SHIPMENTS



This is something that every foundryman wants when he orders his goods.
We are prepared to give you service, quality, and lowest prices on anything from a DUST BAG to a CUPOLA. If you are not using EUREKA BLACKING you ought to. It's the BEST on the MARKET.
EUREKA CORE COMPOUND (a pitch core compound) of 100% purity, mixes much the same as flour and as readily taken from the castings. Will not blow and is cheaper than flour.
No. 48 PLUMBAGO, a high graphitic carbon lead, will do the best kind of work, if you are looking for that kind. Write for latest catalog of Polishers' and Platers' Supplies.

WE would like you to understand the new McDougall Lathe. It is a machine of reserve strength and capacity. It can handle your high "speed" steel tools at their maximum speed. You get the benefit.

Note the headstock construction first. See the very wide bearing surfaces and massiveness. The whole machine from headstock to base is like a solid rock. We have done everything that will make this headstock right. It must wear. It must resist strain.

The big bearings are fitted with deep oil chambers and ring oilers. Your lathe is automatically protected against accidental wear and excessive loosening up of the bearings by the operator's omission of oil. Only when you get wear taken care of, have you a headstock which is able to resist strain. Its wide bearings are not only kept automatically in shop perfection, but they take the greatest strain a cutting-tool can give through the work and a spindle in high-carbon steel. The automatic oil device protects the quality of your lathe output by protecting the bearings, so chattering is impossible

Look at the work of a McDougall Lathe some day. You will see a smooth, clean tool-cut, shining and bright. This shows the even feeding of the work from a firm headstock against a firmly-held tool.

The carriage and apron are non-springing. The action of the tool depends on the solidity of bearing given it by the carriage. This carriage is supported by full "V" bearings, and flat bearings as well. There can be no "lost motion" in the carriage, and none at the cutting edge of the tool.

The tool feed reads to thousandths both ways on the compound rest The automatic feed is of the safety type, so interlocked that your mechanic cannot operate both feeds (screw and rod) at the same time.

Here you have a clean cut from a solidly-held tool working against a solidly-held casting, in a lathe so protected by automatic oiling that it always maintains its accuracy and strength. You can adjust this tool to 1-1000 inch. You cannot break tool or work by accidental operation of both feeds at one time. No breakdowns.

Now look at the tailstock. It has a quick-acting sleeve lock device. This permits quick change of work. In addition the tailstock is secured to the webbed and non-springing bed of the lathe by four bolts with top adjustment. Both kinds of tailstock changes are easy and quick—they save workmen's time.

Take another look at this McDougall Lathe. See how well the gap is supported, and how deep the gap is. Though this is a gap lathe, it is as solid as a standard type, because the base is carried under the entire gap opening. Here you have a gap lathe without a single disadvantage of the gap opening and the deteriorated work it often causes.

Get a McDougall Lathe like this in your factory equipment. Its adjustability, speeds, capacity and practicability make it one of the most perfect machine tools. It is particularly economical where a variety of kinds of lathe work have to be done on a single lathe, because it is a quick-change machine.

Suppose you write us your problem. And, to-day, now. The McDougall lathe will raise quality and lower cost.

The Greatest Labor-Savers on General Manufacturing Drill Work

Pratt & Whitney Adjustable Multiple Spindle Drills

are more flexible and efficient on a wide range of work than any other drilling machines in general use.

The vertical adjustment of drills is an important feature, as uneven wear of drills may be rectified. Also, in drilling work with uneven surfaces, such as bosses, some of which are higher than others, it will be found very advantageous.

The ease and convenience with which the spindles may be set in practically any desired combination in a very few minutes accounts for the wonderful labor-saving possibilities of these machines on work where a comparatively small number of parts are made.

Write for catalog "Adjustable Multiple Spindle Drills," showing many illustrations of drilling operations where these machines are effecting great savings.

Design based on Experience gained from over 500 Machines in use.

The P. & W. New Model Vertical Surface Grinder

1. On many classes of work this machine will grind surfaces cheaper than they can be milled or planed and with better results.

2. 500 machines in use three years after first machine was placed on the market.

3. The Automatic Reciprocating Motion and Rotary Table are features unknown to any other type of surface grinder.

4. The only machine which has adjustment for rotary table so as to maintain perfect squareness with spindle as well as grinding concave and convex surfaces.

5. Driving belt causes no pressure on spindle, thus ensuring perfect and continued alignment of the spindles.

6. The power applied to this machine exceeds the grinding ability of the best wheel.

Pratt & Whitney Co. is prepared to furnish estimates on production, and will also grind samples in order to demonstrate the superior accuracy and finish of which this machine is capable.

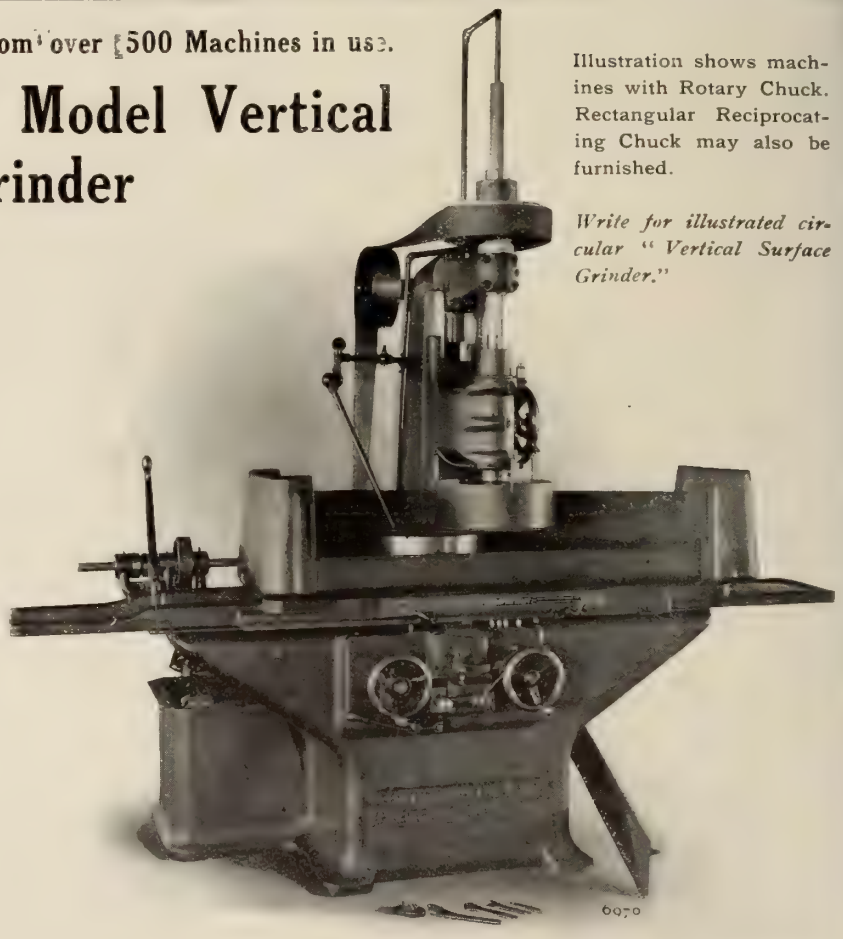

Illustration shows machines with Rotary Chuck. Rectangular Reciprocating Chuck may also be furnished.

Write for illustrated circular "Vertical Surface Grinder."

Westinghouse Adjustable Speed Motor Driving Slotter.

Maximum Economy of Operation

requires your machines to be driven at a minimum power cost, and at the exact speeds necessary to give best results under different processes of work.

Westinghouse Adjustable Speed Motors

direct connected to your machines will give speed changes up to three or four times the slowest speed instantly, the number of speeds being only limited by the number of notches on the controller, which is placed close to the operator.—Nothing could be simpler.

These motors on your machines mean increased profits because of increased operating economy, increased efficiency, increased reliability of service and decreased power costs.

You will find it profitable to avail yourself of the knowledge of our experts in the selection and application of motors; their services are free. A line to our nearest office will receive prompt attention.

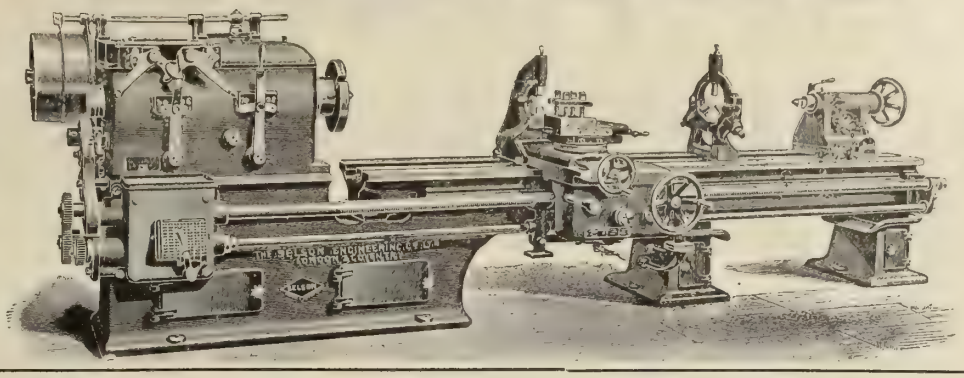
MACHINE TOOL SPECIALISTS AND MANUFACTURERS.

Established 1871

Cable Address: "Selig," London.

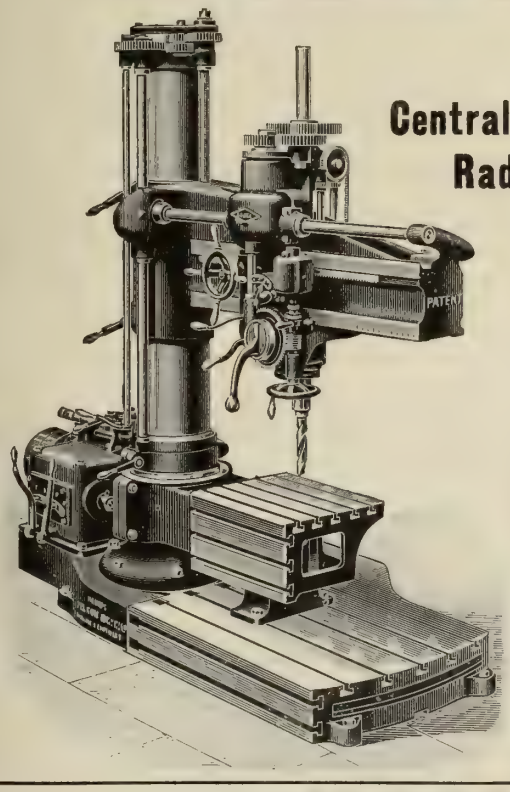
THE SELSON ALL-GEARED LATHE.

Made also with Cone for belt drive.



Bed flat on top with narrow guide along same

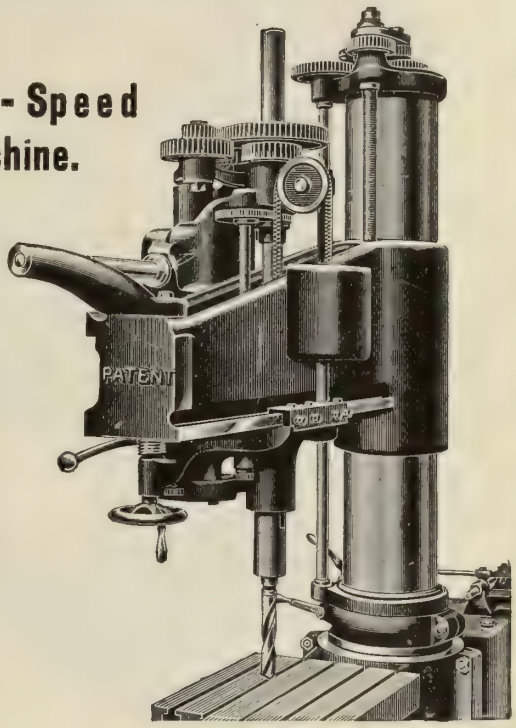
insuring greater steadiness and accuracy, and allowing a heavier cut than with raised Vs.



THE PATENT

Central-Thrust High-Speed Radial Drilling Machine.

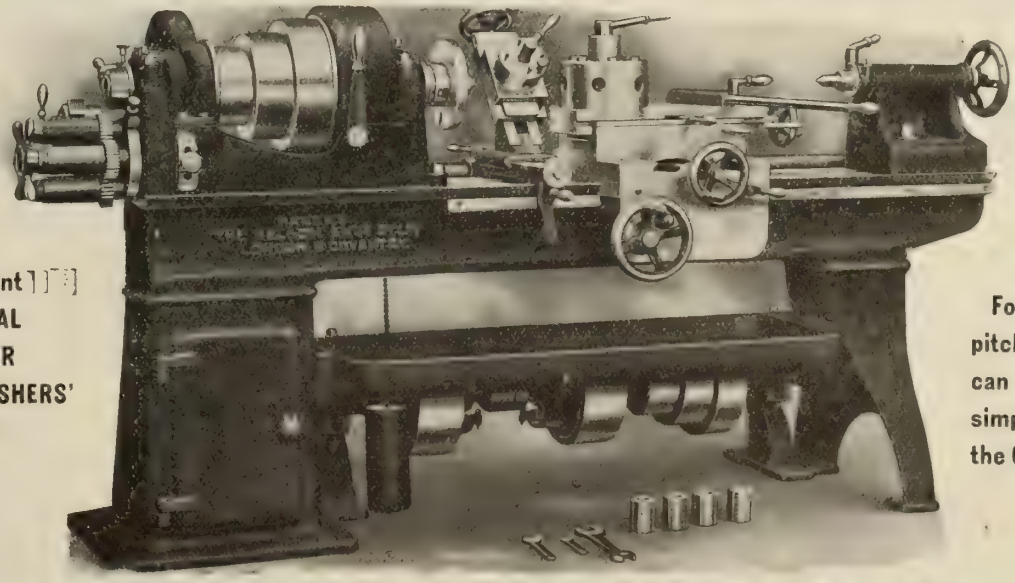
The Spindle being in centre of arm instead of outside, all side strains and breakage of drills are avoided.



The SPECIAL FEATURES of the SELSON TOOLS are

QUALITY.
EFFICIENCY.
STRENGTH.
ACCURACY.

WORKS:
COVENTRY,
ENGLAND.



The Patent UNIVERSAL MONITOR BRASS FINISHERS' LATHE

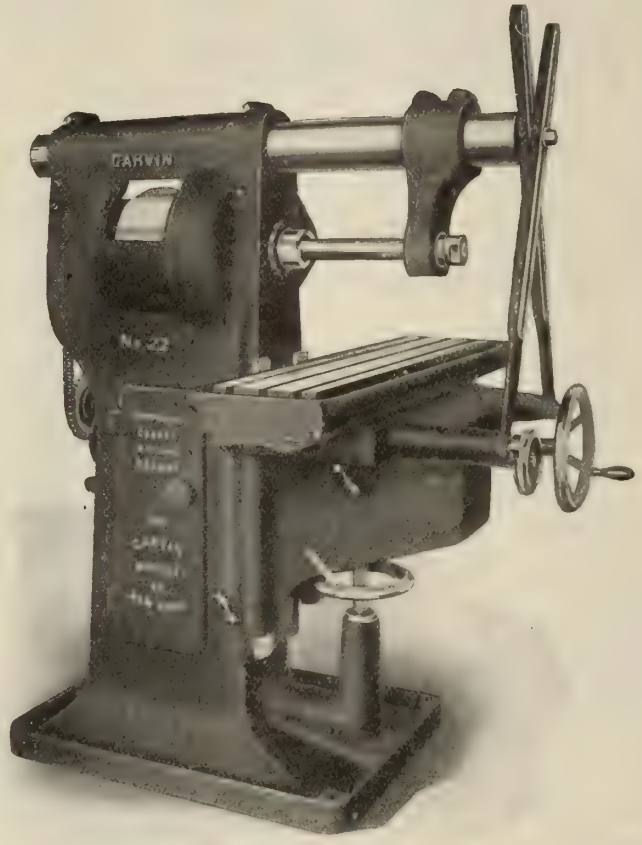
Four different pitches of thread can be cut by simply revolving the Chaser Turret.

85 QUEEN VICTORIA STREET, LONDON, ENGLAND.

We are prepared to make Special Selling Arrangements with active and influential resident agents (keeping stock) in the principal centres.

MOST POWERFUL MILLING MACHINE

(Knee Type)



GARVIN No. 22, Plain Milling Machine, Compound-Geared. Use Code, "Aperient."

The machine shown is the most powerful Knee Type Milling Machine manufactured by us, having Compound Back Gearing whose ratio is 10 to 1, through steel gears. It will transmit 10 horsepower to 14 inch cutters running 20 revolutions on steel castings. The machine has a wide faced pulley of 11 inches in diameter, running loose on the spindle. The power is taken from the countershaft by a 6-inch double belt to this pulley and double-backed-geared back to the spindle. The machine has an arbor 2 inches in diameter, solid, with spindle, thus avoiding a lot of arbor troubles.

DIMENSIONS

Length of automatic feed of table	28 in.
Dimensions inside of oil pockets	43½x9 in.
Vertical adjustment	15½ in.
In and out adjustment	7 in.
Crated weight	3250 lbs.

A VALUABLE BOOK ON INTERNAL GRINDING

FREE

¶ If you are a Machinist, Shop Foreman, Superintendent or interested in any other way in internal grinding, this book contains information which may help you cut down the cost of production, improve the quality of work, or both.

¶ It is written by a man who has made this subject a special study for years, and is full of practical hints on such topics as:—

¶ The latest methods of chucking gears.

¶ Chuck designs that should be avoided.

¶ How to finish internally, hardened bushings having thin walls without distorting them.

¶ How to hold pistons while grinding the wrist pin holes.

¶ And how to handle a variety of grinding problems met in every-day practice.

IF YOU ONLY KNEW THE VALUE OF THIS BOOK YOU WOULDN'T BE WITHOUT IT.

JUST ASK FOR

"Practical Hints on Internal Grinding."

Making a Large Gear Pattern on a

Gardner Pattern Maker's Disc Grinder

How the Teeth Were Made

Cut shows operator producing curve of gear teeth. These blocks 8 in. long by 2½ in. wide by 3 in. high, were first made parallel on Universal Duplicating Gauge and then squared up on end by using Universal Angle Gauge. A simple wooden fixture was made for holding these blocks. By using Circle Generating Gauge, with pin at proper radius, this fixture with block in place was swung against the wheel. Work table was tilted one-half degree to produce required draught. Stop screw made it possible to produce these ninety-six gear teeth exact duplicates.

As near as we can estimate, these gear teeth were turned out in one-tenth the time it would have taken by the old method. Not only was the work done more rapidly, but more accurately and with better finish.

Majority of Other Operations Were Done on the Grinder

The majority of all the machine work on this whole pattern was done on our Pattern Maker's Disc Grinder. All of the segments used in the outside rim were ground parallel to size and glued up on face plate before being put on the lathe. All pieces in spokes were made parallel and squared up on grinder before glueing operation. Round hubs, plates and coreprints ground with taper—on Circle Generating Gauge. All wood fillets and angles fitted on Grinder. Absolutely no hand or machine planing or trimmer work on whole pattern.

Verdict of Foundry and Shop

The foundryman states that this pattern made the best gear castings he ever handled.

The machinists who worked the castings state that they come straighter, more accurate and nearer to size than any others ever machined by them.

Hundreds of operations each day for our Pattern Maker's Disc Grinders in every pattern shop.

Ask for Specifications. Good Deliveries.

Save On The Single Piece As Well As The Big Job

The Bullard Vertical Turret Lathe is not alone a manufacturing machine—the very features which make it a good manufacturing machine also reduce the cost of the individual piece.

The Vertical Turret Lathe is ready to save on face plate work of every description within its capacity. Vertical Construction, Ample Power and Rigidity, Multi-Cutting, Quick Speed Change, Centralized Control, Automatic Lubrication—these cost-reducing factors save on the single piece as well as on the big job. It does not keep the foreman on the jump looking for the right job. Nor does it require an expensive special tool equipment for each job.

Investigate. Find out how much less YOUR face plate work will cost done on a Vertical Turret Lathe.

We'll be glad to put some interesting facts and figures before you.

Send for Treatise on Face Plate Work, No. C-15, NOW.

The Gridley Automatic TURRET LATHE

Combines greater accuracy, a larger output and a wider range of work.

With this Lathe in your shop you will save much labor cost, as one man can attend to several GRIDLEY AUTOMATICS at once, and can use tools tandem when desired.

A greater output can be procured because the rigidity of the tools and general design of machines permit heavier cuts and coarser feeds to be maintained.

The special type of cutting tool has a longer life.

We manufacture our Automatics in both single and Multiple Spindle.

GRIDLEY service means economy. Write us for descriptive catalog. A card will bring it by return mail.

It's RESULTS You Want

WHAT will the wheel do—will it do better work in less time—will it hold its shape—will it cut free and fast—will it show long life—in other words, will it prove to be the right wheel in the right place?

These are the things that the buyer and user of grinding wheels want to know.

Read the answers in the records being made by Carborundum and Aloxite Wheels—records made under every grinding condition—these records are appearing in the advertising pages of this and other trades publications—they are plain statements of the work being done by Carborundum Wheels in grinding cast iron, brass, bronze, etc., and of Aloxite Wheels on steel grinding—we show some of these records in an illustrated booklet—write for it—it helps YOU in getting

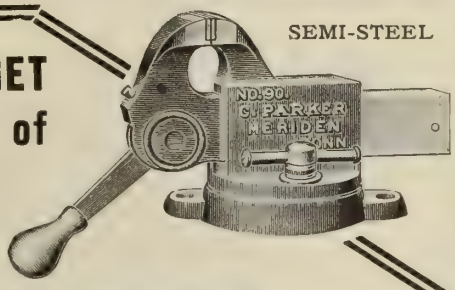
YOU CAN GET the BEST of SERVICE from



The "PARKER" Improved Quick-Action Swivel Vise

This vise introduces a convenience that means economy in every machine shop.

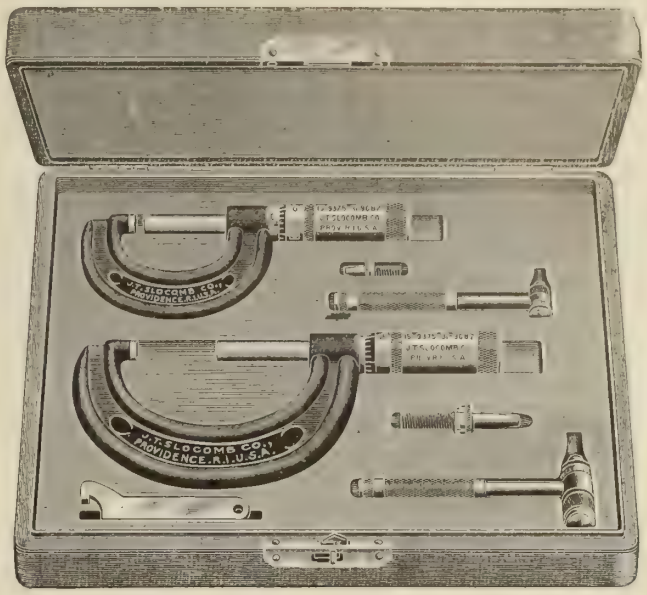
Made from a special blending of steel and best iron.

With "The Parker" you can do your work in less time, as one motion of either right or left hand is sufficient to grasp the article and hold it tight. All parts are interchangeable.

Write for our catalog to-day.

The Charles Parker Co.

MERIDEN, CONN., U.S.A.



Small Inside Micrometers

It is no longer necessary to take inside measurements by use of an inside caliper and outside micrometer which at its best is an unsatisfactory method.

These new Inside Micrometers will measure from 1-2 inch to 2 inches. They are actual measuring tools, giving readings in thousandths of an inch. Measurements can be made throughout the entire depth of the hole, thus avoiding difficulties or errors where measurements are made only at the edge of the hole.

Indispensable when work calls for accuracy in boring, slotting and grooving and internal work in general.

Put up in sets containing Inside Micrometers only, and also in sets containing Inside and Outside Micrometers.

Full detailed description and lists of different assortments given in new catalog No. 13 C. Copy sent on request.

This Guarantee Goes With Every Vise: We fully guarantee all of our Vises to be satisfactory in every particular and will promptly replace, without cost, any parts broken or badly worn when such failures are due to faulty material or construction.

"Stiles" Power Punching Presses

embody strength and rigidity with convenient handling of material. Entire pressure is through solid metal.

Graduated eccentric adjustment facilitates setting dies. Slides are long and well gibbed; watchmakers whose dies are most delicate use Stiles Presses extensively. The fly-wheel can be turned backward to release a punch when stuck in the die.

Built in ten sizes, they are adapted for punching, stamping, forming and bending operations in the economical manufacture of cutlery, hardware, locks, auto parts, typewriters, sewing machines, etc. Catalog No. 2 G, on request.

"Bliss Presses for Every Requirement."

Why Didn't We Protect Those Windows, too, With Fenestra Sash ?

What *water-tightness* is to an ocean liner—
What *burglar-proofness* is to a bank—
What *strength* is to a sky-scraper—
Fireproofness is to a modern industrial building.

It would seem hardly less logical to handicap the watertight compartments of a ship with frail partitions, to offset the 3-foot cement floors of a vault with a wooden trap-door, or to construct a Singer building on a doubtful footing, than it is to build a modern factory of fire-proof construction, equip it with sprinkler-systems, fire-doors and fire-alarms, and then to demoralize the whole chain of expensive and otherwise carefully planned fire-protection by tolerating the weak link of wooden sash.

Scientific factory construction relegates wooden sash to the day of clapboard walls, plank floors and shingle roofs.

Where else can you reasonably class them ?

FENESTRA FIRE PROOF SASH

glazed with ordinary wired glass is positively the last word in fire-resistance as applied to windows.

Common sense dictates that.

Actual fires have proven it beyond question. In a fire at Stoneham, Mass., in September, a building equipped with FENESTRA SASH was practically surrounded by a burning varnish factory. Reglazed after the fire, the Sash were as good as new. Photographs on request.

Remember, too, that FENESTRA SASH also *light* and *ventilate* a building better than any others. They're made to suit individual needs.

If you are interested in the planning or construction of a building where *light*, *fresh air*, and *fire protection* are essentials, let us send you our "Fenestra" Catalog.

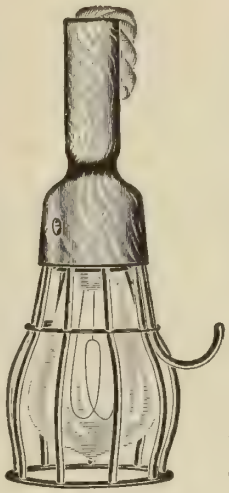
SAMSON



Portable Lamp Guard

Portable Incandescents enable men to work to the best advantage in all the dark corners — facilitate inspection — save valuable time — make more thorough work possible.

The SAMSON is a substantial one-piece portable, at a moderate price. The frame is of steel wires, soldered into steel bars. Handle is of kiln-dried maple. Will stand upright or hang in convenient position for work. Lamp can be removed without taking down guard.

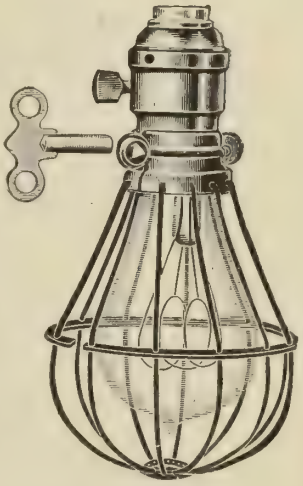
Price, for 16 or 32 c.p. lamp, $1.00 irrespective of quantity.

LOXON

Lamp Guard

The average loss of incandescents through breakage or theft, in shops where they are not protected, would quickly pay for a full equipment of LOXON Guards.

The LOXON is giving full protection and thorough satisfaction in thousands of plants. It locks on with a key, preventing breakage, theft and fire from hot or broken lamps. Costs no more than one of the many lamps it will save.



Price, for 16 c.p. lamps, $2.50 per dozen.
Price, for 32 c.p. lamps, $3.75 per dozen.

We can make immediate shipments of SAMSON or LOXON Guards.

CONVERTED

THE foundation upon which we have built a world-wide business is based upon our policy of seeking and curing troublesome bearings, and otherwise demonstrating the value and economy of Magnolia Metal. Magnolia is not a **SOFT** metal; its factor of safety is far in excess of the requirements of any properly-constructed bearing—and outwears even brass or bronze, giving much better service.

There is a lot of misinformation regarding "hard" bearings.

No matter how hard they are, they go to pieces or give trouble when they get hot—which they generally do.

Magnolia keeps cool, won't squash, stays put, and won't cut.

O. B. LITTELL, 622 Pontius Avenue, Seattle, Wash.
December 7th, 1911

GENTLEMEN—I take pleasure in stating that I am a user of Magnolia Metal and have been for the past two years.

I have put Magnolia Metal to what I consider a thorough trial. The first place I applied the metal was to an emery wheel travelling 1200 R.P.M., and it worked so well that I then applied it to a fan 1470 R.P.M. The next place was to the crank pin of my main engine, and having such good results I concluded to babbitt the cross head brasses. In all the places the metal was applied, not one bearing has been taken up over 1/16 in., and has run from 12 to 15 months.

I have come to the conclusion that Magnolia is surely a riddle; it can be worked like lead and still be as tough as it is.

I was somewhat afraid to try it in my main engine, because I thought it was too soft to stand up to the work, but I have a different opinion now. I have been following this line of work for over 12 years and am sorry that I did not have an introduction sooner.

Yours respectfully, ALLEN J. STOCKE,
Engineer in Charge.

How This Rubber Belting Cuts Production Cost

Don't let slipping belts waste power—drain away profits. Plug up the leaks—save time, money, power, by investigating—installing Goodyear Rubber Belting.

Goodyear Rubber Belting stands for saved energy—***economy.*** Built up of plies of rubberized fabric, cured and vulcanized into the solid piece. Neither slips nor stretches. Has the cohesiveness of rubber with the enduring strength of a specially woven cotton duck fabric from which all stretch has been taken out. It is steam, water, weather and rot proof.

The same high grade materials, the same skillful workmanship and the same years of experience that have built such famous service into the products of the Goodyear Tire & Rubber Co., U.S.A., is doing the same for Goodyear Rubber Belting and our many other rubber products.

GOODYEAR Rubber Belting

High Efficiency Belting

Every size for every purpose—1 inch to 60 inches wide—2 plies to 8 plies thick.

Goodyear Quality Belting

The highest grade made. Heaviest duck, best rubber, seamless, tough, durable. The saving main-drive belt for **Paper, Pulp** and **Lumber Mills**—for **all** mills where the horse power transmitted is large and the demand for tensile strength is great.

Black Diamond Belting

Lighter in weight, lower in price than above, but same in **quality.** Great quantities sold to **Sawmill** trade. Hundreds of mill owners say it gives better service than any other belt ever used.

Red Cross Belting

The ideal belt for **Thresher, Small Sawmill** and **Flour Mill** use. Built to meet competition, yet is far superior to all other third-grade belts because made of tougher rubber, heavier fabric (which means better friction) and better wearing service and cover.

Stitched Rubber Belting

We make this belting in **Quality, Black Diamond** and **Red Cross** weights for those preferring this type of belting.

Elevator Belts

We make a specialty of **Elevator Belts.** Our Leg and Lofter Belts used in hundreds of elevators. Give superior service because of greater strength. Buckets never pull out. Plies never separate. Long efficient service guaranteed.

Conveyor Belts

For conveying crushed stone, grain, coal, ore, etc. Made in all thicknesses of face to suit requirements. Great toughness of rubber face prevents cutting and chipping; insures longest service.

IMPERIAL HIGH-SPEED FRICTION SURFACE BELT

Specially designed for planer, dynamo, generator or fan work where pulleys are small and high-speeded. If we haven't what you want in stock, we'll **make** it—and **remember**

Goodyear Rubber Belts quickly earn their cost in pains and power saved—yet they cost less than the common kind. Let our expert solve your problem. Send requirements or write for catalog tonight.

Our sales of the last four months fifty per cent. greater than those of last year. Defective goods returned only $23.93.

Men in Charge

—Owners —Superintendents
—Managers —Foremen
—Purchasing Agents

¶ These are the men you want to reach with your advertising.

¶ There is a reason why CANADIAN MACHINERY AND MANUFACTURING NEWS is THE medium you should use in a large way to reach these men.

¶ Given a good journal—well edited, illustrated and well printed, the paid-up circulation would be small were not a vigorous campaign carried on, both by mail and personal work.

¶ CANADIAN MACHINERY is well edited, well illustrated and well printed—the one source in Canada of timely, reliable, first-hand information to mechanical men.

¶ But we are not satisfied with simply publishing a good journal. Our thoroughly-trained, salaried subscription men are out hustling for subscriptions in every province of Canada—and getting the business, or we want to know the reason why. In addition, we are represented in practically every railroad shop and other large shops by special agents, who are well paid for every order sent in—and every mail brings orders from these men.

¶ No machine shop, foundry or metal working shop of any class, whether large or small, is overlooked by our subscription plan.

¶ Above is one GOOD reason why you should not overlook this journal as your strongest aid to more business in 1912. There are many others.

Want to talk it over? Write us.

CANADIAN MACHINERY
AND MANUFACTURING NEWS
143 University Ave., Toronto

NO PAINT *Ever* Needed on this Roofing

The need of paint or gravel on a roofing is positive proof of its weakness—positive proof that the materials in the roofing would dry out, rot, rust, decay or otherwise deteriorate without such protection—positive proof that the roofing itself can't last long unless protected with a **mineral.**

Instead of a perishable animal or vegetable material only **temporarily** protected with a **thin layer of mineral,** such as paint, slag or gravel, J-M Asbestos Roofing is **one solid mass** of **minerals.** Not a particle of perishable material in it.

J-M Asbestos Roofing consists of layer-on-layer of pure Asbestos Felt securely cemented together with genuine Trinidad Lake Asphalt. Asbestos is a rock, or stone, and, of course, stone needs no coating to make it last. And the Asphalt Cement between these stone layers is the same material that has withstood the severe duties of street paving for forty years. So J-M Asbestos Roofing is an **all-mineral** roofing.

J-M ASBESTOS ROOFING

is the only ready roofing that never requires a single cent's worth of coating or other protection. Its first cost is its only cost. Other ready roofings are a continual trouble and expense—for the paint and gravel wash and blow off and have to be renewed every few years.

Because of this mineral or stone construction J-M Asbestos Roofing is also rust-proof, rot-proof and acid-proof. And fire that will melt iron won't ignite this roofing.

We'll sell you J-M Asbestos Roofing direct from our nearest branch if your dealer won't supply you.

GET THIS CURIOSITY FREE

We want you to see the curious Asbestos Rock which yields the long, soft, pliable, yet practically indestructible fibres from which we make J-M Asbestos Roofing, Theatre Curtains, Stove Mats and hundreds of other Asbestos products. We know it will convince you better than anything we can say that a roofing made of this indestructible stone must also be practically everlasting.

Simply send a postal to our nearest branch and say "Send sample of Crude Asbestos and your handsomely illustrated Catalogue No. 303."

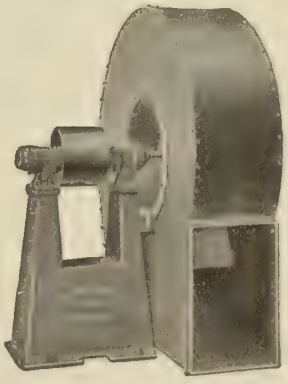
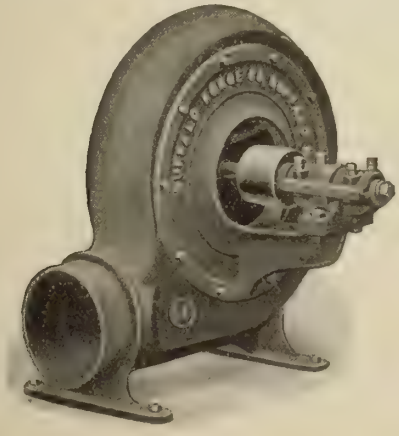
"Buffalo" Slow Speed Reversible Exhausters



Not a slow-speed fan in name only, but so economical in operation that in every installation a saving of power from 15 to 50% has been shown. The difference soon pays for the entire investment. The housing is reversible, so that it can be moved to discharge up or down, left or right, or any direction between. Motor, pulley or engine driven.



Buffalo "B" Volume Blowers

Developed and perfected by the best fan experts, these stock size Blowers and Exhausters have been brought up to a standard never before reached. Put your exhaust proposition up to our engineers; their services are free. Address Dept. 10.

PUMPS

The superior excellence and splendid results shown by

"FAIRBANKS-MORSE"

pumping machinery are largely due to the fact that for many years we have manufactured Hydraulic Machinery of all descriptions. We are therefore able to build pumps which are properly designed and adapted to every-day use. This is of the greatest importance in a first-class pump, for the usefulness of an engine may be lost if the pumping machine is badly designed.

You will get all these important features when you purchase a "FAIRBANKS-MORSE" pump.

Let us solve your pump problems.

Prominent Features of Forge Practice in English Shops

By Joseph Horner

The writer is well and favorably known through his contributions to the editorial columns of the leading technical journals of Great Britain and the United States. Concerning Canada, he is no stranger, having on previous occasions furnished highly instructive information to readers of Canadian Machinery on important developments in mechanical engineering practice. The subject of the present series of articles will be found extremely interesting, enabling, as it does, a close comparison between British and Canadian methods to be made, and perhaps profitable hints extracted.

TO talk about forge practice involves dealing with classes of work which are as highly differentiated as are heavy marine engine castings and small brass castings; or as the work of the heavy turnery and machine shop, and that of the automatics. There is little in common between the methods of production of massive forgings and those of small dimensions, while forgings of medium size form another class apart from the others. The methods suitable for one great group are not available for the others.

Outside this general classification, there is in each much scope for variation in methods, and in selection of machines and appliances. A great deal of hand-forged work is still done in general engineering shops when the volume of repetitive work is not seemed sufficient to render the cost of stamping dies remunerative. There is a large quantity of this in which but a few similar forgings are wanted, and when these are of fair dimensions, little help can be derived from the use of dies except for those sectional parts of the work which would occupy the most time in finishing on the anvil.

These dies may then be kept as a constantly growing stock outfit, both with a view to lessen labor, and to impart rapid finish to forms which are identical in different jobs. Eyes for tie-rods are very common examples, also valve bridles, levers of many shapes and so on; bosses and webs being the ever-recurring shapes. In such cases, the forgings or portions of them are often prepared roughly at the anvil and finished only in dies. More frequently, the power hammer is used for roughing down with setts, fullers, flatters, punches, etc.; these latter being especially handled or prepared for the purpose. Special spring swages and tools may also be used, and by taking another heat, the final correction and neat finish are imparted in the die or dies. These are frequently of cast-iron, because easily and cheaply made, or of cast steel. They are not always attached to the anvil or the tup, but often simply placed on the former, with or without strap attachments to prevent them from shifting. If there is a top die it may be located on the bottom one by means of dowells or guide strips. Alternatively, it may be attached to the tup.

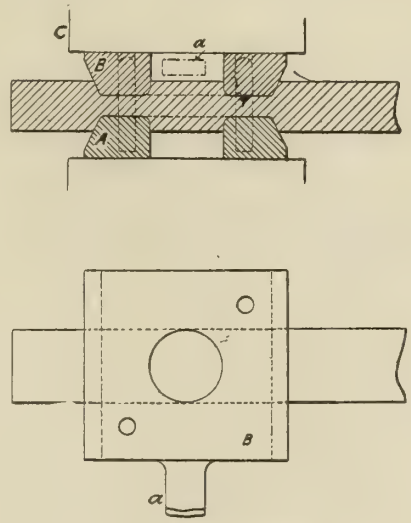

Fig. 1—Forge Practice.

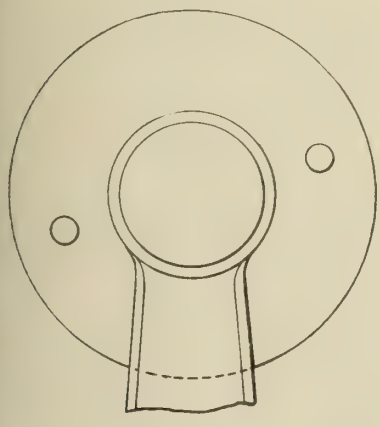

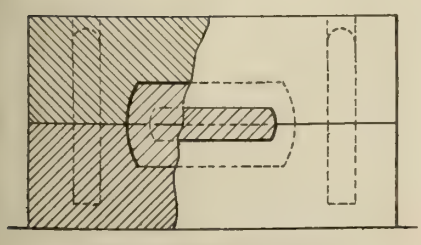

Fig. 2—Forge Practice.

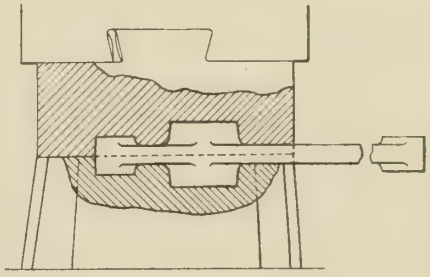
In almost all English engineers' smithies, these dies accumulate in large numbers, yet they are the only real economical aids which can be utilized, apart from a heavy outlay which would not be justified by the numbers of similar forgings required. They save much laborious correction with swages and flatters, and ensure uniformity of dimensions as well as the neat finish of identical parts. The work turned out in these shops with the assistance of cast-iron and steel dies is thus usually that of finishing only. A few examples will represent the largest proportion of this class of work done in English engineers' smithies.

Examples of Dies.

Fig. 1 is an example of a couple of simple dies used for finishing the circular portions of bosses on opposite sides of a lever. The lower die A, merely lies on the anvil; the upper one, B, being gripped by a long handle A, centred by holes dropping over dowells, and driven down by the tup "C." Both dies are steel forgings, their holes being bored. This is representative of a large quantity of work in which a bar or an odd chunk of suitable cross section is fullered down under the power hammer. Corners are cut with a hot sett, when bosses, bossed ends, or forked ends have to be produced. Drawing down of webs and stems is done on suitable setting



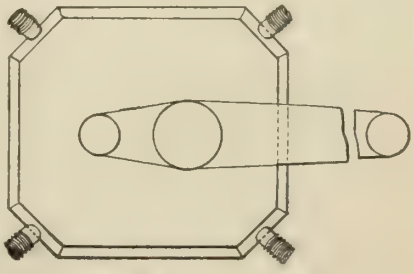


Fig. 3—Forge Practice.

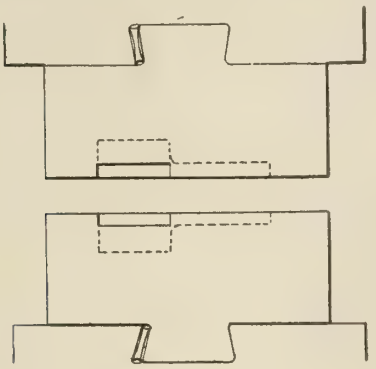
blocks with hammer blows. With another heat, the finish is imparted between dies made in designs suitable to the requirements for bosses, stems and lumps for forked ends, and for punching holes and recesses. The drawing down which is done under the hammer directly need not be illustrated. It is done with or without preliminary fullering. The fuller used may be either a spring or top fuller. The forging or only sections of it are put into dies for the corrective and finishing operations.

If a top die is not attached to the tup it is usually essential to dowell it to the bottom block, without which precaution the bosses on opposite sides of



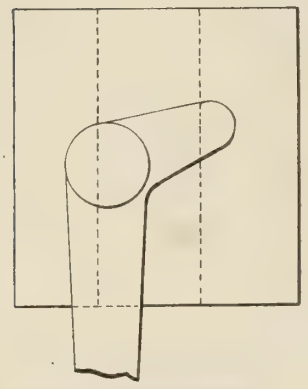


Fig. 4—Forge Practice.

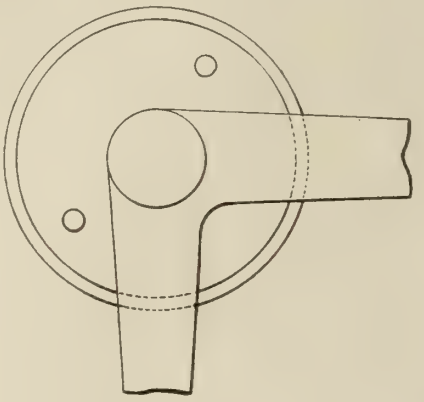
the web are likely to get out of alignment. The dowells should be in the lower portion to avoid the filling up of the holes with the scale and dust from the forgings. The dies not only finish the bosses but also portions of the web which lie adjacent. This is usually all that is done in the dies; the main portion of the web of a long lever being finished away from the dies, directly between the tup and anvil.

A bossed end is shown as finished in a pair of steel dies, Fig. 2. The bottom die is simply laid on the anvil, the top one dowelled to it and gripped by a pair of special hoop tongs. Fig. 3 is a pair of steel dies finishing two adjacent bosses on a lever; done thus because they are close enough together to be treated in the die. The boss at the outside end is finished in a separate die. The bottom die in this example is held on to the



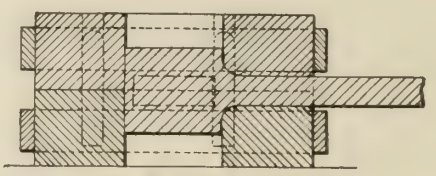


Fig. 5—Forge Practice.

anvil with the usual four poppet screws employed on drop hammers, by means of which it can be brought exactly in alignment with the top die and held with a dovetail and wedge in the tup. In the finishing of webs, some drawing down is inevitable, and its amount must be estimated correctly beforehand, when bosses are situated at both ends, or when their centres will not come right. These may be checked with a fixed trammel, or by rule measurement as the work is proceeding.

Fig. 4 is an example of steel dies attached to tup and anvil, and finishing the bent portion of a lever, including its boss; the opposite end being treated in another die. Fig. 5, illustrates cast iron dies also finishing a bent lever previously roughed out at forge or hammer. The bottom die lies on the anvil; the

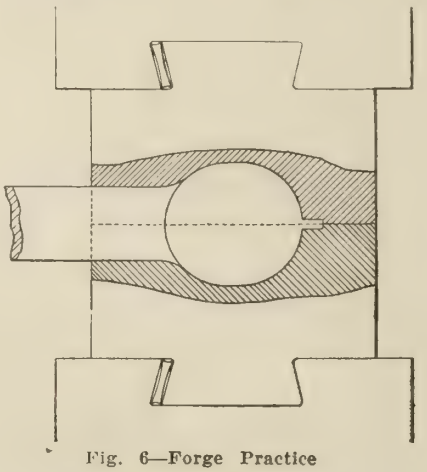

Fig. 6—Forge Practice

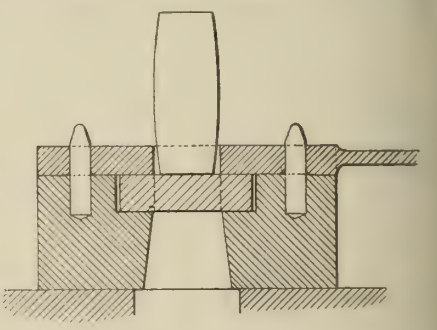
top one being dowelled to it, lifted off and on with the special hoop tongs already mentioned. The top die is struck by the tup.

When levers are set at angles, this is not done by stamping the angle in the die as would be usual in small drop forged work; levers like those in Figs. 4 and 5, being commonly forged straight and bent under the tup. One end is gripped edgewise between the anvil, and the tup brought down lightly on it; and the free over-hanging end being then set with sledge with or without the help of a setting block, after which the lever is put into the dies as shown, for final correction and finish.

In the engineer's smithy two pairs of dies are often used for articles of similar shape, though smaller work of simi-



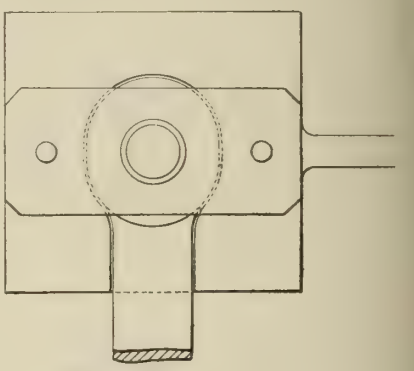


Fig. 7—Forge Practice.

lar kind would, when made in the regular stamping shops be forged at one operation. Thus, Figs. 6 and 7 show the two stages of making the eye of a tie-rod, which, when finished is welded to the straight bar. The welding length of stem is drawn down from a bar of about the same cross-section as that of the eye, and the eye itself is roughly trimmed by cutting off the corners with a hot sett. It is then finished to shape in the dies, Fig. 6, the surplus metal passing partly into the stem, partly into a recess made in the dies and partly as a fin into the joints; provision for receiving which may or may not be made. The fin having been knocked off, the eye is dropped into the bottom die, Fig. 7, and the punching templet for the eye laid on; being centred by its dowell

holes. The punch is then placed and driven through by the hammer. The eye metal is mostly pushed out as a burr, but a little extension of the eye takes place laterally, allowance for which is provided by making the die rather larger than the eye when first inserted as indicated.

In this class of forging, little trouble is experienced from the presence of fins

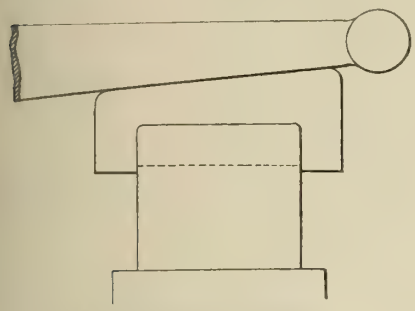

Fig. 10—Forge Practice.

which are thrown out so extensively in drop forging work. Stripping dies are, therefore, seldom used, and any fin that may form is generally cut off with a hot sett. Punching is usually done with a loose punch in this kind of work, although in regular die-stamping shops, handling small forgings, the punches are made solidly with the dies.

Fig. 8 illustrates another example of punching, that of a square hole. Oblong or elliptical holes are quite as readily made. In this case instead of the loose guide-plate put on the flush-topped die of Fig. 7, the top die becomes a guide for the punch. The punches are either bellied or straight tapered, both forms being used at the forge and anvil. The hole in the bottom die is tapered to permit of free delivery of the burr, and the depth must be sufficient to give it clearance below the forging.

In Fig. 8, the dies are of steel and a handle is welded on the top one for lifting purposes. In Fig. 9, and also in Fig. 5, cast-iron dies are shown. In these, one handle, or two, when considerable weight has to be lifted, are frequently cast in. As these project awkwardly, an alternative is to core holes in their ends for the insertion of loose handles, Fig. 9. Cast-iron dies should in almost all cases be bonded. Cast-steel dies, unbonded, are frequently substituted, but the working parts come out rougher and require more trimming than do those of cast-iron. The bonds are made and shrunk on hot, but are liable to shift in consequence of the jar of the hammer blows; hence, the outsides of the dies are sometimes tapered slightly so as to be larger in the portions towards which the bonds tend to shift.

Fig. 10 illustrates how the tapered portions of webs, etc., are finished with a loose block laid in another block on the anvil. Blocks of different angles can be substituted. Fig. 11 shows a curved lever similarly set on a curved block. In article II. the practice of die stamping shops will be considered.

Abrasive Wheels

By J. H. Williams.

WHILE the art of making abrasive wheels is not a new one, it is only of recent years that the various processes have been worked out on a scientific basis, and the importance of the grain

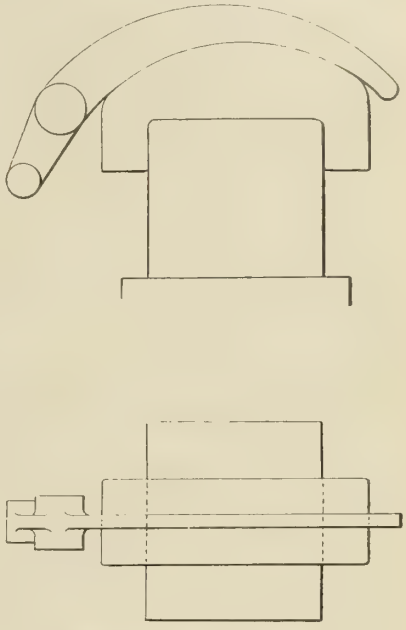

Fig. 11—Forge Practice.

and grade in relation to the speed of the wheel and the work to be performed fully understood. Manufacturers, however, are now realising that it is a saving of both time and money to use wheels of the very best quality, running at the

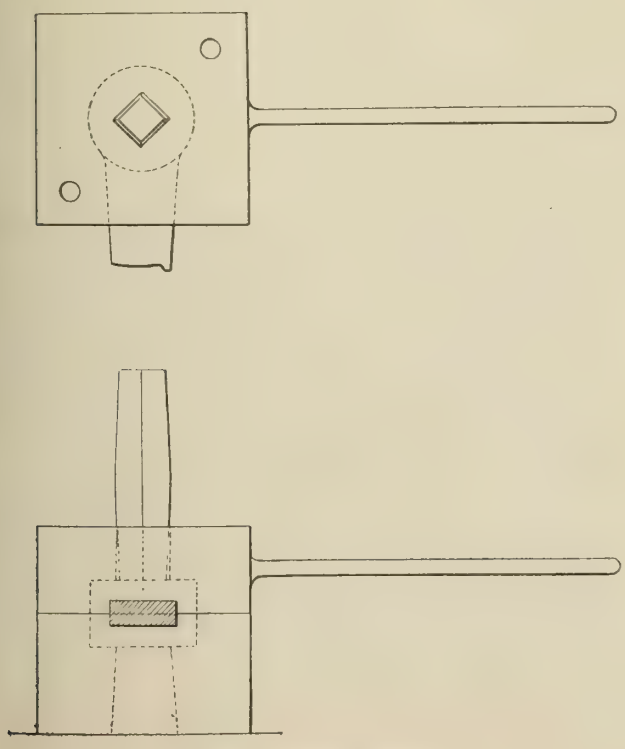

Fig. 8—Forge Practice.

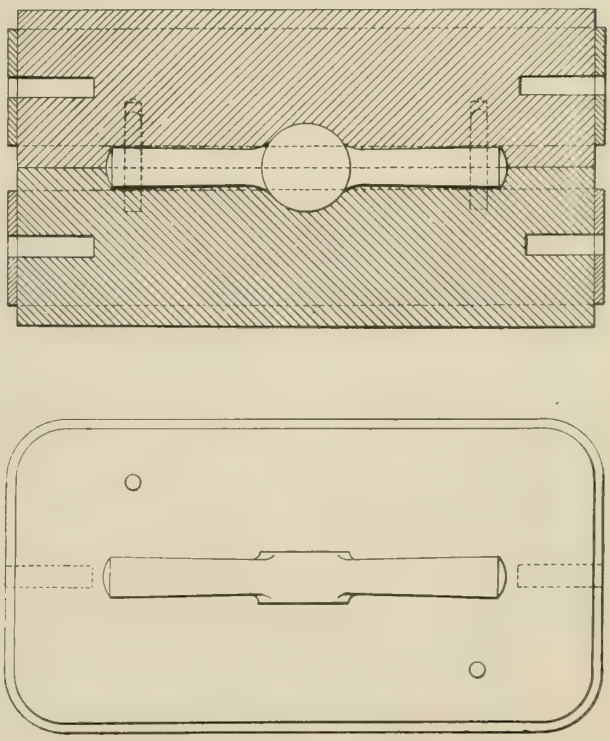

Fig. 9 -Forge Practice.

correct speed on machines of heavy and substantial construction. Occasionally factories are seen where wheels of the same size may be running on various machines with a difference in speed of 50 per cent. or more, and with a corresponding difference in durability and efficiency. Since most makers of abrasive wheels now grade their product so as to give the best results at a peripheral speed of from 5,000 to 5,500 feet per minute, it can be readily seen that if run at half that speed, the wheels will do less work and wear out much faster than if properly speeded, even if made of good material by the best process.

The Ideal Wheel.

It has been said that the ideal wheel should contain only cutting materials. The only wheel that can fulfill this condition is the vitrified wheel, the bond of which will cut by itself, without the addition of emery or other abrasive material. Probably 85 or 90 per cent. of the wheels now used are made by the vitrified process. All other processes, such as the silicate process, are substantially alike; the emery grains being combined with some binding material of an adhesive or gummy nature, such as shellac, rubber, asphaltum, celluloid, silicate of soda, etc. The mass is tamped or pounded in an iron mould, and is afterwards dried or baked in an oven at a low heat. Most tamped wheels require the addition of a certain amount of corundum or other brittle material to secure the desired cutting qualities.

Vitrified Wheel Manufacture.

Vitrified wheels require no tamping or pounding. The emery grains are mixed with various vitreous clays and spars, the amount of which, in proportion to the emery, determines the grade of hardness of the finished wheel. Water is added and the mixture stirred until of the proper consistency, when it is poured into rings of sheet iron, no tamping being employed. The sheet iron rings or hoops stand on slabs of plaster of Paris which rapidly absorb the surplus moisture in the mixture. The wheels are allowed to partially dry and are then placed on a special machine having a horizontal revolving table and a flat-nosed tool which travels parallel to the latter. On this machine the wheels are shaved down to approximately the correct diameter and thickness. They are then taken to an oven or drying room where they remain until absolutely dry. After careful packing in clay saggers in the kilns, the latter are fired, the temperature gradually rising to about 2,500 degrees Fahrenheit. This great heat fuses and vitrifies the clays and spars, which on cooling form the bond that holds the grains together. The kilns, after firing, are very slowly cooled down; the process taking several days, depending on the size of the kiln. When cool, the wheels are put in a face lathe and dressed perfectly true all over. The holes for the arbors are then brushed with lead to the proper size.

The wheels are next placed on a special testing machine consisting often of an ordinary double floor fitted with wood-lined steel boxes, in the which the wheels revolve, thus eliminating all danger of damage should a wheel burst. By means of a variable speed motor or by a system of several countershafts, the spindle of the machine is given a wide range of speeds, all wheels, no matter what their diameter, being tested to run at a peripheral speed of not less than 9,000 feet per minute, which gives a stress of 250 lbs. per square inch. When run at the usual speeds of from 5,000 to 6,000 feet per minute the stress on the wheel is from 75 lbs. to 100 lbs. per square inch, so that this test gives an ample factor of safety. Having successfully passed the test the wheels are carefully inspected and are then ready for boxing and shipment.

Points to be Noted.

When ordering abrasive wheels, the purchaser should give the manufacturer all the information possible as to what the wheels are expected to grind and under what conditions. To many this may seem unnecessary; but to the maker of the wheel it is important. It is to his interest to suit his customer's requirements; and while some prefer a hard wheel with a long life, others find it more economical to use a softer, quicker-cutting wheel. Any preference in this matter should be mentioned at the time of ordering.

When once a satisfactory grain and grade for any particular class of work has been established, a good manufacturer should be able to reproduce it indefinitely. As a general rule, the harder the metal to be cut, the softer the grade of the wheel, on account of the tendency to pull the grains from the bond. However, it is economical to use a grade that will get out the work in the shortest possible time, since the labor cost is higher than the wheel cost.

A wheel that quickly glazes, and so requires constant dressing, is manifestly too hard and will prove expensive in the end, since it is worn out by the dresser instead of by the work.

General Observations.

Complaint is sometimes made by users that a wheel is softer at the centre than at the rim. This is obviously impossible with a vitrified wheel, which is not tamped. The true explanation is that when the wheel is worn down it is not running at its proper peripheral speed and does not cut so freely. Hence the impression is given that it is soft at the centre. Where practicable, wheels should be changed, when worn, to a faster running machine, so that their surface speed may remain approximately constant. A good vitrified wheel is not affected by heat, cold or water. In fact, water increases grinding production, and when grinding tools, should always be used. If it is necessary to keep the work and machine from rusting, soda water may be used.

It is becoming more and more widely recognized that the abrasive wheel is a "cutting" wheel and not a "grinding" wheel. Its action is analagous to that of a milling cutter with thousands of fine pitched teeth. This should be borne in mind, and the wheel given proper attention in order that the greatest efficiency may be got out of it.

POWER COSTS.

THE following statement shows the cost of power in a number of prominent Canadian cities. It was embodied in a report made by a special Board of Trade Committee from data secured through investigation:

Toronto—Hydraulic; 92 miles; light, 8c. to 3c., with discount of 10 per cent.; power, 5c. to ½c., with discount of 10 to 20 per cent.

Hamilton—Hyraulic; 32 miles; light, 2¼c., discount, 10 per cent.; installation free, power, $1.20 per h.p. per month.

Calgary—Steam and hydraulic; 35 miles; light, 9c., discount 15 per cent.; power, 2c. to 1 1-10, with discount of 10 per cent.

Winnipeg—Hydraulic; 37 miles; light, 7½c., now 3c.; power, 4c. to 1c.

Edmonton—Steam coal, $3 a ton; light, 8c.; power, 8c. to 3½c.

London—Steam and hydraulic; 150 miles; coal at $3 a ton; light, 4½c.; power, 3½c. to 1¼c. with discount of 10 per cent.

Vancouver—Steam and hydraulic; 17 miles; light, 11c. to 4c.; with discount of 20 per cent.; power, minimum charge of 2c.

Victoria—Steam and hydraulic; light, 13c. to 9c.; with discount of 1c| per kilo-watt; power, 7c. to 2c.

Hamilton—Coal, $3 per ton; gas, $1.00 per 1,000.

Calgary—Coal, $2.62½ to $4 ton; gas, $1.75 to $1.35 per 1,000.

Winnipeg—Coal, $3.50 per ton; gas, $1.30 per 1,000; discount 10 and 25 per cent.

London—Coal, $3 per ton; gas, 95c. per 1,000.

Vancouver—Coal, $3.75 per ton; gas (a), $2 per 1,000, discount 25 per cent. (b), $1.50 to $1.25, discount 10 per cent.

Victoria—Coal, $3.75 per ton; gas (a), $2 per 1,000; (b), $2 to $1.50, discount 25c.

The Big River Lumber Co. Plant, Big River, Saskatchewan

By Allen Norgrove.

This plant, although located away back in the woods, as it were, is of the most modern type for its purpose, being laid out for convenience and flexibility, with reserve equipment to avoid stoppage or extended delay and inconvenience through accident or breakdown. A careful perusal of the various features will be found edifying to operators and manufacturers alike, showing as it does the wisdom of a proper initial installation for a given duty.

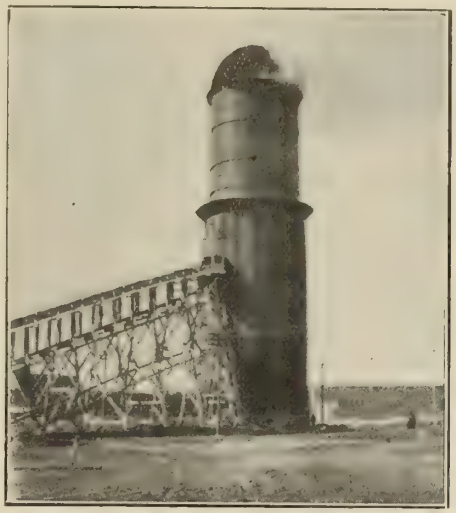
THE power-house, a brick building 80 x 152 feet, lies north of the sawmill and is covered with galvanized corrugated iron roofing. It is divided by a brick wall running lengthwise, forming on the east side the engine room and on the west side the boiler room.

The Boiler Room.

This contains twelve horizontal tubular boilers 18 feet by 72 inches, built by the Muskegon Boiler Works, Muskegon, Mich. There is space left for two more boilers, should it be necessary to install them. The boilers are hung in the usual way to strong steel "I" beams resting on steel posts, which, in turn, rest on a concrete foundation. They are set in pairs in Ashley steel casings, which give a neat appearance, none of the brick-work being visible. One stack connects each pair of boilers, its dimensions being 4 ft. diam. x 100 ft. high above the breaching.

Each boiler is connected through a 6-in. pipe long radius bend to a 30-inch header, from which one 12-inch line leads to No. 1 engine, one 10-inch line to No. 2 engine, one 5-inch line to No. 3 engine, two 8-inch lines into sawmill, one 4-inch line to boiler feed pumps, one 6-inch line to fire pump, a 4-inch line to the big whistle, and a few smaller lines for sawdust conveyer engine, flue blowers, etc. The boilers are also equipped with "Dutch oven" furnaces, having 8 x 6-ft. grates for burning sawdust, shavings, etc. The latter are brought in from the mill by a steel chain conveyor, which runs through fire-room, and what is not consumed in the furnaces is carried over to the fuel house, at the north end of the power-house, by the same conveyor.

When the sawmill is shut down, or not supplying enough fuel, return is made from the fuel-house by a second



Big River Lumber Co.—Refuse Burner

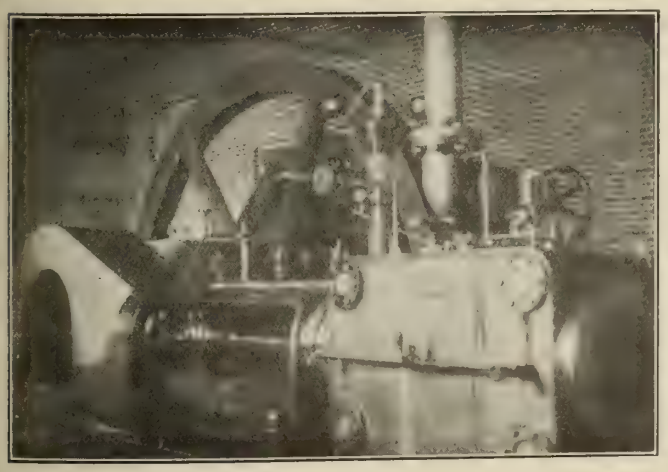
steel conveyor, driven through a "Jewel" high-speed automatic engine placed on the steel floor of boiler-room, which is level with the oven tops and engine-room floor. Under this steel floor a track is laid for wood supply and taking out ashes, etc. Each boiler has two blow-off valves, a Crane blow-off valve next to boiler, and an asbestos-packed cock outside of this, both being inside fire-room. Each boiler has a separate blow-off pipe leading to the river bank, about 70 feet away.

Engine Room.

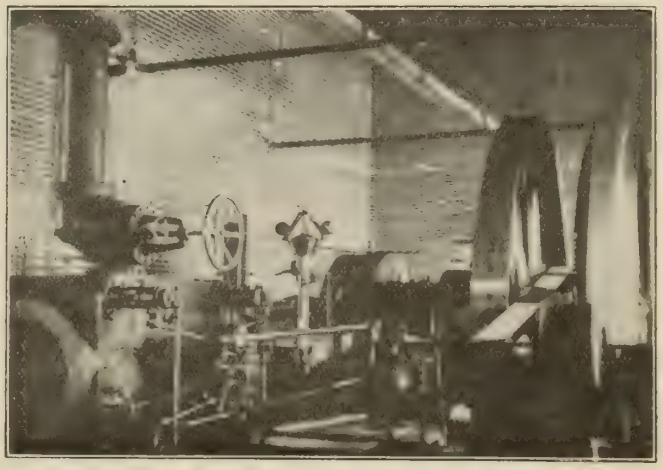
The engine room contains three simple Corliss engines of the double eccentric, long range cut-off type, built by Filer & Stowell, Milwaukee, Wis. No. 1 is a 38 x 60 inches cylinder, running 61 rev. per minute, with flywheel 24 feet diameter, 68-inch face. This engine drives the sawmill with a 66-inch leather belt 145 feet long, supplied by the Beardmore Belting Co. Toronto. In case the engine should get on centre, it is fitted with barring-over cylinders. These consist of a cylinder placed on each side, near the rim of the wheel. On the cross-head end of the piston-rod is a grip which holds the rim, and lifts it the length of the stroke of the cylinder—about two feet. When reversed, it lets go, sliding down the rim until piston reaches the bottom cylinder again, ready to repeat the same operation. The cylinders are fitted with piston valves for ease of operating, and cushion is obtained by valve and port construction, as in loading and turning cylinders in sawmills. By having one cylinder on each side of wheel, it matters not to which side the belt runs, as one cylinder is large enough alone.

No. 2 Engine.

No. 2 engine has a 30 x 48 inches cylinder, and runs 100 rev. per minute. It is direct connected to a Crocker-Wheeler alternator of 1,000 k.v.a., 600 volts, 3-phase, 60 cycle. This engine furnishes power for planing mill, machine shop, etc.



Big River Lumber Co.—16-in. x 30-in. Engine.



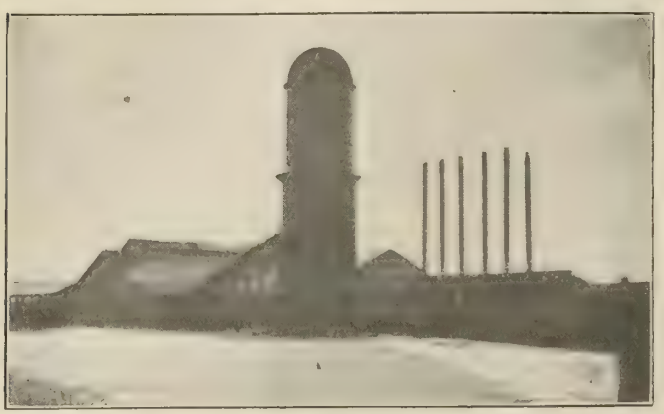
Big River Lumber Co. 30-in. x 48-in. Engine.

No. 3 Engine.

No. 3 engine has a 16 x 30 inches cyclinder, and runs 120 revs. per minute. It is direct-connected to another Crocker-Wheeler, 3-phase, 600-volt, 60-cycle generator of 150 k.v.a. This engine carries the lights and a few small motors; in fact, it takes care of the load up to its capacity, at which point it is taken over by the 30 x 49 inch cylinder engine.

For town lighting, current at 600 volts is carried by a line running at right angles to the streets; a transformer placed on each street supplying a 110-volt circuit, on to which the house circuits are tapped. This system works very well, as none of the streets are long, and no difficulty is found in keeping the circuits balanced.

The other engine room equipment consists of a 2,500-h.p. "Wainwright" derwriter pump, situated on river at water's edge for fire protection. Its 8-inch discharge comes through basement, and is connected so that it can feed direct to boilers in case all three boiler feed pumps should by any means become disabled. The boiler feed pumps are arranged to discharge into the fire line, each of them having a separate suction to the river. They can feed the boilers either through the heater, or



Big River Lumber Co.—Saw Mill from Town Site.

Big River Lumber Co.—Saw Mill Looking from River.

Switchboard.

The switchboard is of finest blue Vermont marble, and consists of eight panels: one for measuring instruments for each machine, and which consist of ampere-meter for each phase, voltmeter, ampere and voltmeters for exciters. The exciter switches, and rheostats are also on the same panels. One panel carries the main switch and relay for each machine, and the other four are for distributing circuits. The switchboard stands out about four feet from wall, thereby allowing current, potential, transformers, oil switches and all fuses to be placed behind it. Current at 110 volts is used for lighting, and that used in power house and sawmill is transformed inside of power house by three single-phase transformers in engine room.

closed feed water-heater, a large oil filter, and the heating coils required to keep the room at the temperature at which the oil will flow. The oil flows by gravity from filter to engines, then to a tank in basement, from which it is pumped to the filter again, thus keeping down the oil bill.

Basement.

The basement contains the feed-water pumps, and all the valves for controlling the heating, water and drainage for the whole plant.

This is a necessity in such a severe climate (60 degress below zero), as the frost goes down in the ground more than eight feet. The boiler feed pumps consist of three Filer & Stowell duplex pumps of the Worthington type, 10 x 6 x 10, with 5-inch suction, 4-inch discharge. There is also a Fairbanks un-

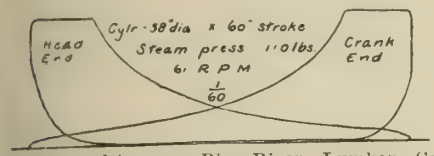
direct, and any one of them can be turned into any line independently. There is a tee on the suction pipe near pumps, where hot water from the huge refuse burner can be turned in with a head of 75 feet.

The suctions to the boiler feed pumps and discharge from fire pump come up through a concrete tunnel into the basement. Live steam to fire pump, the exhaust from boiler feed pumps, drains from header, water columns, and heating systems pass out again through this same tunnel, thereby keeping the water pipes from freezing, and maintaining open water for fire pump intake. This is only 10 feet from the pump, and makes an easy lift. All pumps are fitted with Mason regulators. The branches from the water line are all taken off the main in basement, the largest one sup-

Bird's Eye View of the Town of Big River.

Big River Lumber Co., Rafts of Logs in Front of the Mill.

plying the sawmill service. This is an 8-inch line from which branches lead out to 24-hose-gate valves located in and around the mill. There are two 50-foot lengths of hose and a nozzle in rack close by each. Another 8-inch line leads up town, with hydrants and hose to protect planing mill, and a feed line to refuse burner. All lines are carefully laid out so that any one of them can be shut off and drained in the basement. This layout cost a large sum to install, as it required many valves to

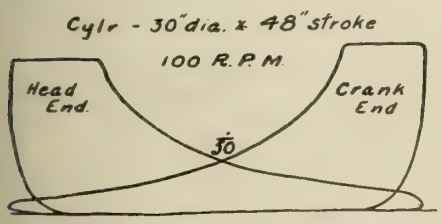


Indicator Diagram—Big River Lumber Co. engine.

secure the necessary service and control.

Exhaust Piping.

The exhaust piping is laid out with the like precautions to save a shutdown, a tee being used under each engine cylinder, one side of which is piped outside with a back pressure valve, the other side being piped to the feed-water heater line, with a gate valve for each engine. This line is of 14 inches spiral riveted galvanized pipe, and can either be made to pass through feed-water heater or by-passed through sawmill to hot pond. This pipe also collects all drains from the steam feed cylinders, as well as from some of the smaller cylinders in sawmill. The log deck cylinders, which consist of 6 cylinders for log turners, 3 cylinders for loaders, and 3 cylinders for log kickers, have a separate 5-inch exhaust line, also leading to the pond. As steam sett-works are used on the carriages, steam guides and



Indicator Diagram—Big River Lumber Co. engine—Back pressure valve open.

straining devices on the band-mills, and steam cylinders for raising skids and bumpers (in all 42 steam cylinders in sawmill), there is quite a quantity of exhaust and drains to be taken care of.

A 6-inch line off main exhaust before it enters heater leads to heating coils in sawmill, from whence a 3-inch line leads to the planing mill. About 2 pounds pressure is carried during day time, and about 4 pounds during night time. This is obtained by using a 14-inch back pressure valve on the exhaust line. The planing mill is heated by placing coils between the machines at places best suited, the machines producing the necessary circulation. The sawmill has coils and a fan placed in room on north side of the building. Air is drawn in by the fan through the coils, and then forced out through light galvanized iron piping of 4-ft. diameter at fan, reducing to 6 inches at smallest outlet.

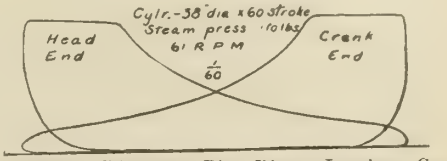
Refuse Burner.

The refuse burner stands north of the sawmill in front of power house. It is a large iron structure, 34 feet inside diameter, 140 high, with an 18-inch water space for 75 feet of its height. It has a large opening on side next mill for refuse conveyor to empty its contents, and on the opposite side a smaller one for shavings from planing mill. It stands on a concrete and firebrick foundation, and the water space is fed by four 3-inch water pipes at bottom and one 3-inch pipe up near conveyor opening. Four 4-inch pipes serve for the overflows, which are carried to hot pond by an 8-inch line. A 6-inch line is taken from near the middle of its height to suction of boiler feed pumps. This is taken up inside near the top, then through the shell and down the outside, with vent at highest point inside to prevent syphoning. A double screen is provided on top for arresting sparks, and a flare is placed at top of outer sheet of water-jacket to catch water when boiling, and return it into water space. All necessary man and hand holes are provided for cleaning out, also doors for regulating draught and cleaning bars through burner proper, beside doors for cleaning out ashes and regulating draught below bars. This outfit was by the Muskegon Boiler Works.

Sawmill.

This is a large frame building on cement footings, 273 x 125 ft., with lath-mill on one side, 32 x 127 ft., and lumber sorting shed and transfer platforms, 118 x 296 ft., on the other. It contains three bandmills and carriages (with 12-inch steam feed cylinders), one vertical and one horizontal re-saw, four edgers, two sets of trimmers, all the necessary live rolls and chains for automatically moving lumber from one machine to the next, until boards are loaded on cars ready for the piling ground; also, log chains for bringing in the logs; steam cylinders for loading, turning, etc. The mill has a capacity of from 3,800 to 4,000 logs per day of 10 hours. In addition, there is a large slasher for preparing slabs for lath mill. The lath mill is capable of turning out about 90,000 per day of 10 hours.

Above the main floor of the mill is the filing room, where all the saws are sharpened, tempered, brazed, and worked up to cutting shape. This room has its own engine, so that it may be run independently. Below is the basement, which contains all shafting, belts, pulleys, friction clutches, steam cylinders, and piping, etc., for driving machinery, besides all chains and conveyors for carrying away sawdust and refuse. In the basement, also, are work benches, tool rooms, racks for oil cans, and the belt room. In this latter place, belts are made up and repaired, it being eq-



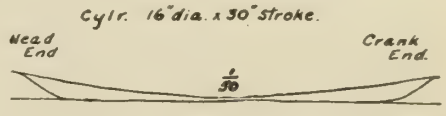
Indicator Diagram—Big River Lumber Co. engine.

uipped with a full line of tools for cutting, scraping, glueing, riveting, etc.

Planing Mill.

This is a frame building, 209 x 100 ft., situated about 350 feet away from sawmill, with C. N. R. tracks running alongside. It contains 10 planers, 1 moulder, 1 edger, 2 trim-saws, 1 table saw, and 2 re-saws. Overhead is the filing room, where all the saws are kept in cutting trim, and at one end is the grinding room, where all the knives are sharpened and shaped.

It is equipped with Sheldon's (Galt) patent blower system for gathering up shavings and delivering same to fuel house. By this system, shavings and sawdust are collected by two 75 h.p. motor fans, having pipes to each machine and other parts of the building where shavings fall. Delivery is into a large separator, the air passing out through the top, while the shavings fall to the bottom and pass into a machine with revolving cylinders open at each end. These, in turn, come under the separator, and fill with shavings, then



Indicator Diagram—Friction load Big River Lumber Co. engine.

under the pressure pipe of a large rotary blower. At the same time the other end of cylinder is directly over discharge pipe leading to fuel house. This pipe is 13 inches diameter, and is fitted with a valve and branch pipe to refuse burner, when shavings are not needed for fuel. The power equipment in planing mill, including back heads for planers, filing, grinding rooms, and blower system, consists of 28 Crocker-Wheeler motors, ranging all the way from 75 h.p. to 10 h.p.

Machine Shop.

The machine shop is a large building situated about 300 feet from sawmill. It contains one large planer, 36 inches x 16 feet; one large and one small lathe, shaper, nut and bolt machine, power hack-saw, drill presses, tyre bender, pipe cutting and threading machine, etc. There is a blacksmith's shop adjoining. The machine shop is driven by a 50 h.p. motor, and the blacksmith's shop is equipped with a small motor-fan for blowing fires.

Round-house.

There is a round-house for steam log haulers, containing a locomotive-type boiler, a Marsh pump, and the usual equipment for washing out and repairs. A blacksmith shop is also attached.

Manufacturers of Equipment.

All the sawmill machinery was supplied by Filer & Stowell Co., Milwaukee, Wis. Boilers and burner by the Muskegon Boiler Works Co., Muskegon, Mich.; piping and valves by the Canadian Fairbanks Co. and the General Supply Co., both of Winnipeg; belting by the Beardmore Belting Co., Toronto, through the General Supply Co., Winnipeg. Planing mill machinery was all supplied by the Berlin Machine Works Hamilton, Ont., together with Sheldon's patent blower system. All the electrical equipment was supplied by the Canadian Crocker-Wheeler Co., St. Catharines, Ont.

Big River Township.

The town is situated east of plant, on high ground, the streets running north and south. It is well governed, clean and sanitary, with comfortable dwellings. There is a large boarding house, butcher's shop, post-office, railway station, schoolhouse, hospital, two churches, main office, a large retail store, and a big wholesale warehouse, with spur into same from main track. This latter institution is a necessity, as there are 25 lumber camps to be served besides the town. The population numbers between 800 and 900, while large numbers are continually going to and from the camps.

The town, with its stores, offices, churches, schoolhouse, etc., as also the sawmill, planing mill, and all machinery therein, the boarding house, lumber yards, tracks, etc., were carefully planned, laid out and erected under the supervision of Mr. W. A. Graham, the present superintendent. There are two mail and passenger trains per week, in addition to freight and supply trains. The company owns a gasoline car, which plies between Big River and Prince Albert.

GEORGIAN BAY CANAL.

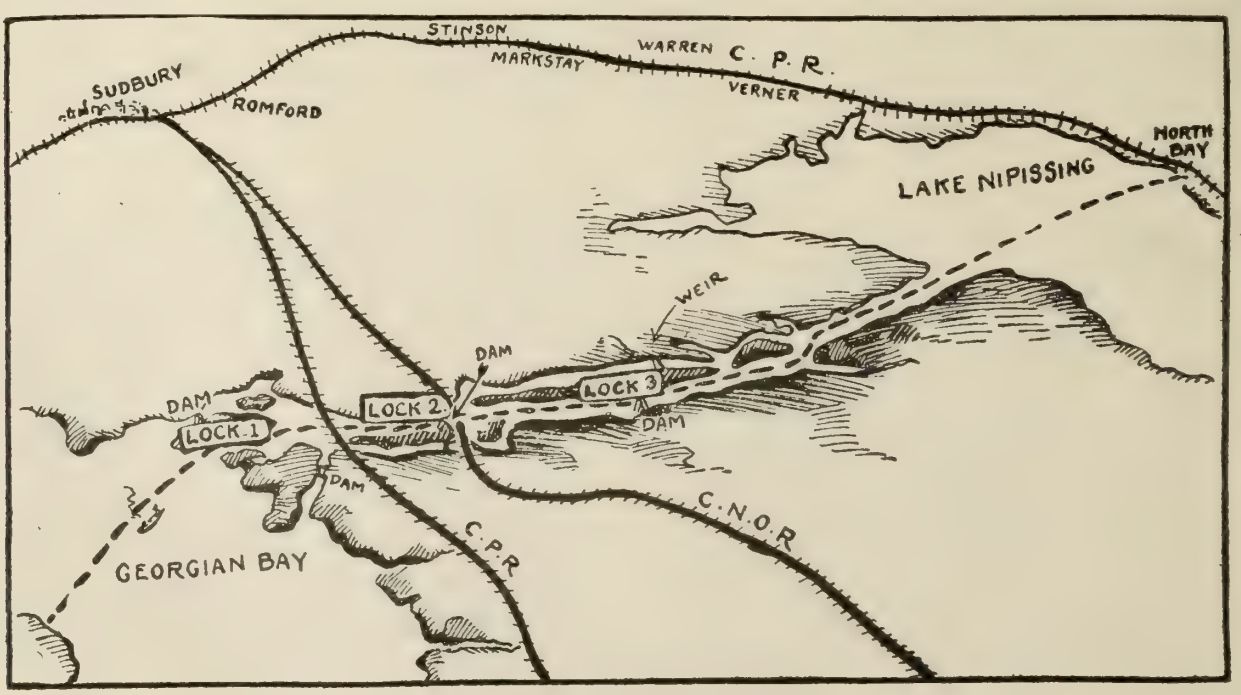
OUR illustration of the French River from the Georgian Bay to Lake Nipissing was that recently submitted to the Federal Government at Ottawa. A deputation from the Ottawa Valley urged the Cabinet to begin work on the French River section of the Georgian Bay canal. The diagram illustrates what the northern people want, and why. The citizens of North Bay are particularly interested in the project, and they are supported by the Associated Boards of Trade of Ontario in the request to make navigable the 49 miles from the Georgian Bay to Lake Nipising. Should the undertaking be carried out, North Bay, the gateway of New Ontario, would become a grain depot, being favorably situated on the C. P. R.; while the T. & N. O. line from the G. T. P. and the C. N. R. will come in from the east. It is estimated that 35,000 horse power can be developed from the locks in the French River stretch of the proposed canal.

STEEL CAR PLANT AT PORT ARTHUR.

Eastern Canada financiers and manufacturers, headed by F. B. McCurdy, J. R. McLeod and F. M. Brown recently signed an agreement with the City of Port Arthur for the erection of a modern steel and wood car plant, with a capitalization of $5,000,000. These people are organizers of the Nova Scotia Car Company, Limited, which is operating successfully in Halifax. The company will employ 1,000 men, and as the plant is located at the head of navigation and the centre of Canada, it will be in a position to supply freight and passenger cars to the various transcontinental railways at the points where most needed.

Chas. H. MacMillan, general superintendent of the Dominion Steel Co., has resigned. He has been connected with the steel plant as superintendent for five years. It is not known who will succeed him.

George Smith, who has been superintendent of the steel foundry department of the Londonderry Iron & Mining Co., Nova Scotia, has resigned to assume the position of superintendent of the Dutcher Works plant of the Prince Steel Co. Milwaukee, Wis.



Three Locks on Georgian Bay Canal.

DEVELOPMENTS IN MACHINERY

A Record of New and Improved Machinery Tending Towards Higher Quality and Economical Production in the Machine Shop, Blacksmith Shop or Planing Mill.

AUTOMATIC STARTING CONTROL.

Gould & Eberhardt Motor Driven Crank Shaper.

THE machine illustrated is a 24-inch Gould & Eberhardt crank shaper, driven by a five h.p. Reliance adjustable speed motor of the armature shifting type, with a speed range of 300 to 1,500 r.p.m. It is equipped with automatic starting control and Reliance speed dial.

Speed Changes

Speed adjustments with the Reliance adjustable speed motor of the armature shifting type are obtained by the mechanical shifting of the motor armature. This is controlled by the hand wheel A, on the equipment illustrated. Turning this hand wheel causes quick, but smooth changes in the cutting speed. With the speed properly set for a given operation, the motor may be stopped and started as often as desired without further attention to the speed adjustment. This is possible with the armature shifting type of motor due to the fact that the starting and stopping is entirely separate from the speed control.

Cutting Strokes.

By using a motor with a speed range equal to the ratio of the back gear, an unbroken range of cutting strokes is obtained from 4½ to 115. The unlimited number of cutting strokes throughout this wide range combined with ample power at all speeds insures maximum output for any size cut on any kind of material.

Starting and Stopping.

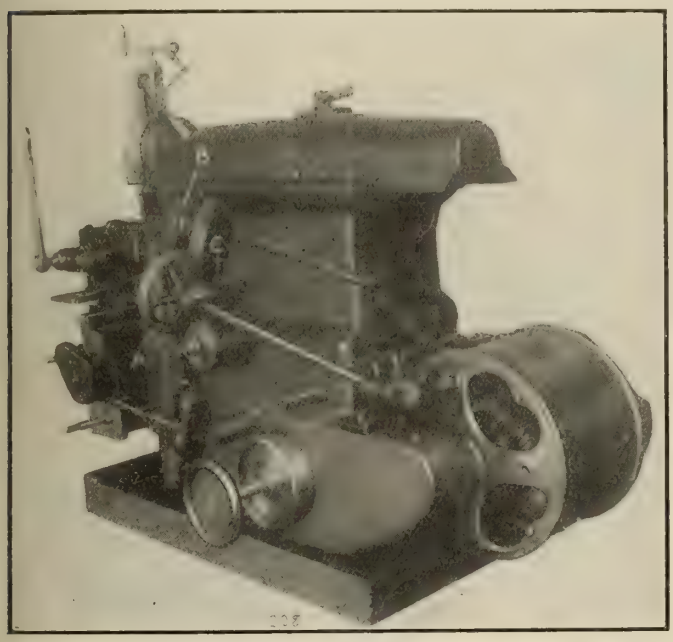
The starting and stopping of the motor are controlled by an automatic starter through the drum switch, B. This switch has three points: start, off and brake. To start the motor, it is simply necessary for the operator to throw the switch to the starting position When the switch is thrown to the "off" position, the power is shut off and the time taken for the machine to stop will depend upon the time required for friction to overcome the momentum of the moving parts.

When the switch is thrown to the brake position, the motor is automatically brought to a stop almost instantly. This simple and positive method of stopping eliminates the necessity of a clutch, which, it will be noted, is not used on the shaper illustrated. With this method, the motor is never running idle, thus unnecessarily wasting power. The starter is of the series control type, and automatically takes care of all starting conditions. It removes all possibility of abuse to the motor or starting equipment. The starter itself is mounted on a nearby post. All wires are carried in conduit tapped directly into the drum switch, thus, doing away entirely with exposed wiring and contacts about the machine.

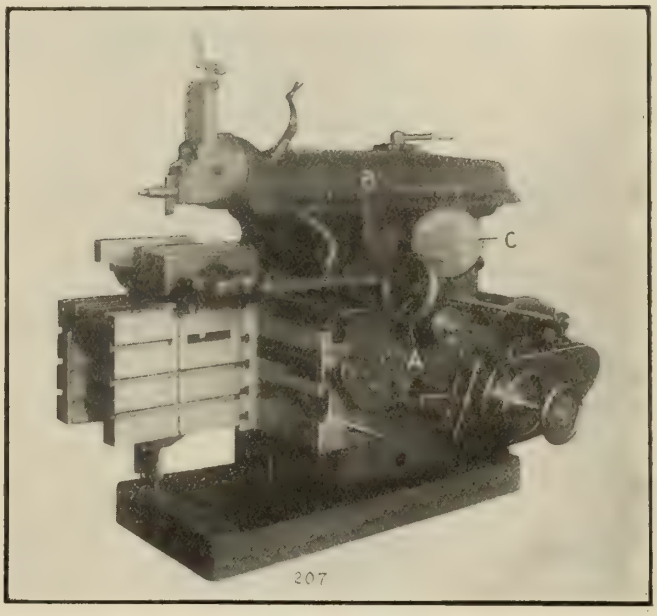
Reliance Speed Dial.

The Reliance speed dial C is a device which permits of instantly setting the motor speed to give any desired speed at the cutting tool. It is of the nature of a circular slide rule, and in the case of a shaper takes account of all the variable factors, such as ratio of drive, length of stroke and cutting speed desired.

The method of using the dial is exceedingly simple. Assuming, on the shaper illustrated, that it is desired to take a cut of 40 feet a minute with a stroke of 20 inches. The small knurl on the front of the dial is turned until the indicator which moves about the top scale is opposite 40; this being the desired cutting speed in feet per minute. The motor armature is then adjusted by turning the hand wheel A until the pointer of the dial is opposite 20, which is the stroke to be used. The dial not only serves as a guide in setting the speed accurately, but is always in plain sight as a definite indication to the foreman or inspector of the speeds in use by the operator.



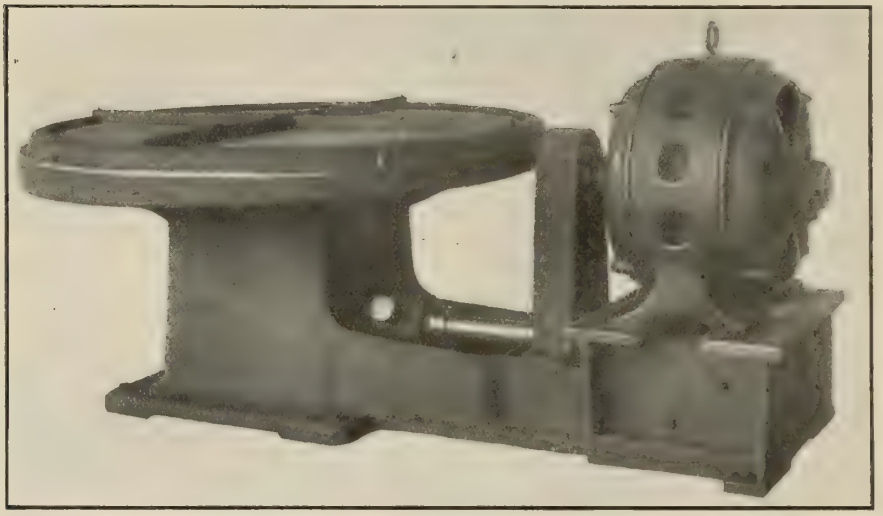
Motor Driven Crank Shaper.



Motor Driven Crank Shaper.

MOTOR DRIVEN VERTICAL SPINDLE DISC GRINDER.

THE accompanying cut shows a new motor driven disc grinder recently put on the market by the Gardner Machine Co., Beloit, Wis. The machine is their large vertical spindle type, with 53-inch diameter disc wheel. The feature illustrated is the arrangement for direct connected motor drive.



Motor Driven, Vertical Spindle Disc Grinder.

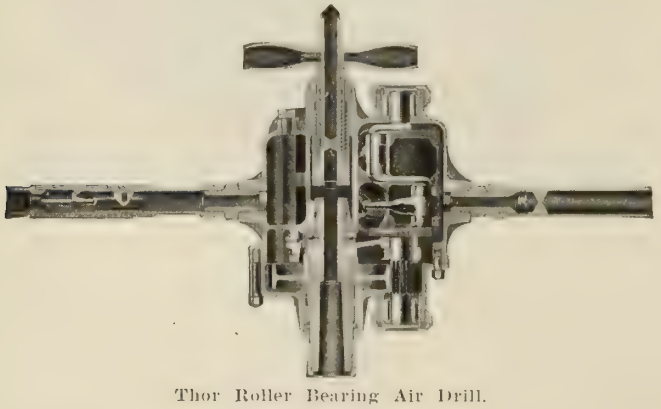
A 15 h.p. motor mounted on pedestal at the right hand end drives the main shaft of machine by silent chain. The shaft drives disc wheel spindle through bevel gears, which are fully enclosed and run immersed in oil. The motor pedestal is made in different sizes to accommodate various makes of motors. A guard covers chain and gears. The starting box is attached to rear base of machine, but does not show in cut. When these machines are installed in plants having no dust exhaust system, an exhaust blower is furnished; the driving pulley for same being attached to a driving shaft midway between shaft collar and silent chain gear. The disc wheel is driven at 500 r.p.m., and the complete machine weight is 4,500 lbs. These grinders are made in the same size for overhead or underbelt drive; the motor driven type being often found more convenient when it is desired to place machine under a hoist or craneway. Such a location is convenient, as the work done by these No. 24 machines is generally of a large and heavy nature

THOR ROLLER BEARING AIR DRILLS.

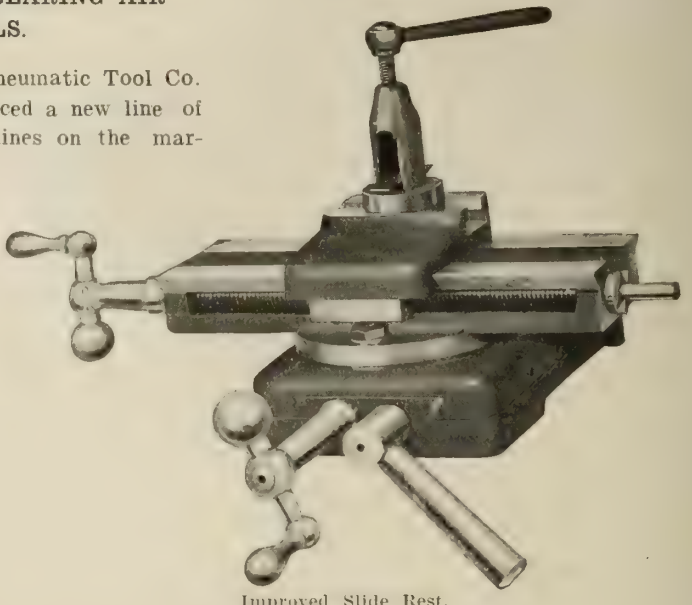
THE Independent Pneumatic Tool Co. have recently placed a new line of portable drilling machines on the market, known as the Thor Roller Bearing Piston Air Drills. These machines possess the same general features which were used so successfully in former types of Thor drills, such as corliss valves, telescopic screw-feed, removable crank chamber plate, and large air chamber. The size of the spindle in most cases has been increased, but the most radical improvement is in the crank shaft bearings, connecting rods, eccentrics and eccentric straps. The crank shaft has been greatly strengthened, and anti-friction roller bearings are provided for same. The rollers are of ample length and diameter and are retained in a machine brass cage. The bushings have a slip fit into the casing and are hardened and ground. The crank shaft has rounded ends and end thrust against a hardened plate which reduces friction.

On account of the increased size of the crank shaft, and ample size of rollers, the centre bearing is dispensed with. The eccentric is smaller in diameter, and being mounted on the crank shaft, still further reduces friction. The toggle and connecting rod used in former types has been replaced with a one-piece connecting rod, similar to that used so successfully in the Thor Nos. 8 and 9 close corner drills. Roller bearings are also provided for the idler or planet gears in the compound drills, and an improved shifter mechanism is used on all two-speed machines.

The accompanying illustration shows this drill with roller bearings on each end of the crank shaft and one-piece connecting rod. These tools are made by the Independent Pneumatic Tool Co., Chicago, whose Canadian representatives are, H. W. Petrie, Toronto, Montreal and Vancouver.



Thor Roller Bearing Air Drill.



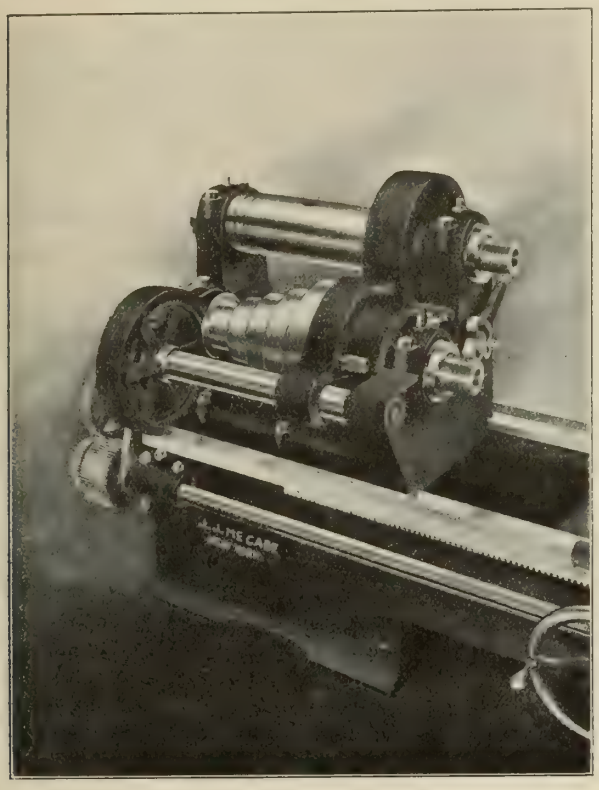
Improved Slide Rest.

BLOUNT IMPROVED SLIDE REST.

THERE is described and illustrated herewith the new Improved Slide Rest manufactured by the J. G. Blount Co., Everett, Mass., for use in connection with their 11-inch swing lathes. This rest embodies all the up-to-date features of such a tool, being so designed that both the cross and lateral feed screws are not exposed to chips and dirt. The handle for the lateral feed screw is detachable and may be used on either end. The graduated swivel is located between the

upper and lower slide, being held in position by two tee bolts, which is the method used on an engine lathe carriage.

The rest, held rigidly to the lathe bed by an eccentric clamping device, which is a distinctive feature of the Blount line, has a lateral feed of 7½ inches, a cross feed of 5½ inches, takes tools 7-16 by ¾ inch, and will allow a piece of work 7½ inches diameter to swing over it.



Two-in-one Double Spindle Lathe.

TWO-IN-ONE DOUBLE SPINDLE LATHE.

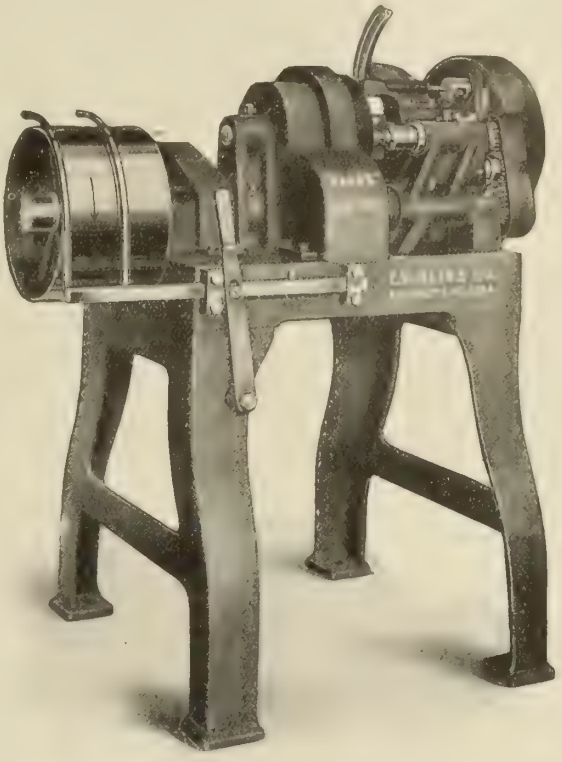
THE many improvements and added features to be noted on the McCabe two-in-one double spindle lathe, have increased its popularity among manufacturing and repair machine shops generally. This particular tool combines the capacity of a triple-geared 4¾-inch swing (geared 72 to 1) and that of a 26-inch back-geared lathe. To accommodate the standard gauge of locomotive drivers, the swing of the large lathe has recently been increased to 54 inches, and that of the small lathe to 32 inches. Steel cut gears are used throughout while the design and constructional detail are such as to cope with the severest high speed duty service. All parts are duplicated and made interchangeable; this type machine being the firm's one speciality, which is made in large lots at a time. The builders are J. J. McCabe, Hudson Terminal, 30 Church street, New York City.

AUTOMATIC THREAD ROLLING MACHINE.

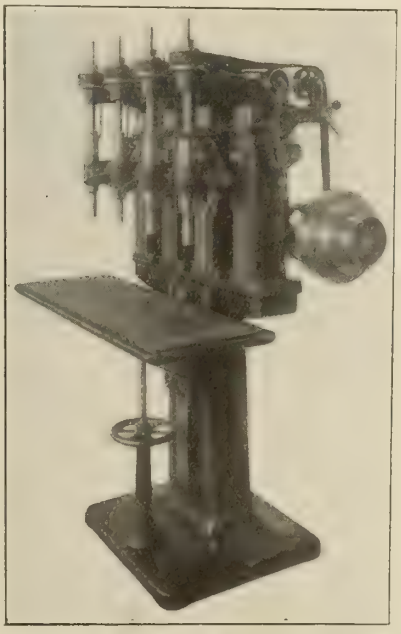
THIS illustration represents a new type Automatic Threading Machine recently designed and built by the E. W. Bliss Co., of Brooklyn, N.Y. It has been designed especially for rolling threads on long drawn shells of small diameter and comparatively light stock.

The machine has four spindles revolving in a horizontal turret, the turret being revolved intermittently by a Geneva movement and the spindles continuously by spur gearing. The spindles are successively brought into position for the various operations; the first or upper one being in front of the feed tube, where the shell is pushed in and on to the chuck; the second is in front of the thread rolling chuck, the third or lower one is the unscrewing device which consists of two leather covered rolls held by spring pressure against the shell, and revolving in a direction to unscrew and discharge it when finished. The chucks are made so that the drawn shell just fits over the thread before rolling. The fourth position is idle, after which the chuck returns to the feed tube again.

In threading, the chuck is so supported as to prevent springing, thus insuring a perfect thread throughout the entire shell length. The machine takes tubes up to 1-inch diameter by 1¾ inches high, and has a capacity of 80,000 in ten hours; it being only necessary to drop the shells in the feed tube.



Automatic Thread Rolling Machine.



Automatic Feed for Drilling Machines.

AUTOMATIC FEEDS FOR DRILLING MACHINES.

THE Dwight Slate Machine Co., Hartford, Conn., have recently put on the market a multiple spindle drilling machine embodying some unique features in automatic feed and releasing devices. The machine is equipped with either of two feeding mechanisms, one of which is actuated by cam and the other by worm and gear.

The cam driven feed machine is de-

signed particularly for the drilling of small and medium size repetition work that can be rapidly and conveniently exchanged in fixtures and jigs. To further increase the output of the machine, the cams are not keyed in line on the feed shaft. In a four spindle machine they would be keyed on the quarter or at 90 degrees. This arangement results in feeding the spindles in progressive order.

Thus, due to the fact that each feed is controlled by cam, the feed return is automatic, and the idle time for exchange of work is practically eliminated. The feed shaft is driven through a change gear box which provides for three speeds of feed for each of three spindle speeds. Through a series of levers, which constitute the automatic release and safety devices, the cam operates a spur pinion which meshes into a rack attached to the spindle. One revolution of the cam is the factor which limits the throw of the feed arm, and consequently the depth to which a hole can be drilled. This limit is 1½ inches for the four-spindle machine in the accompanying cut. The automatic safety device is attached to all spindles and acts independently on each. An increase pressure at the drill point will automatically throw out the feed. Rapid and convenient adjustment for various sized drills is provided. To a great extent this eliminates the amount of breakage of twist drills.

Each spindle has an independent endless belt drive. The adjustment for drilling different depths of holes is very simple and convenient. All bearings are of the oil well type. The levelling of drill points is also provided for by the vertical adjustment of the spindles. The elevation of the table is provided for, by means of a screw and hand wheel.

The automatic feed by worm and worm gear incorporates other features. The depth to which a hole can be drilled is increased from 1½ inches to 5 inches. In this machine also, the adjustment for the automatic release for any depth of feed is not only quite simple but rapidly accomplished. In this case the releasing device disengages a latch arm which allows the worm to fall out of mesh with the gear. When overload occurs, the safety device operates on this latch arm also. The worm gear is keyed to a shaft which is connected to the spindle by means of a rack and pinion. The capacity of this machine is somewhat less than that of the cam driven feed machine but its range of work is correspondingly increased.

Wm. M. Preston, who for the past six years has been general manager, secretary and director of the Canadian Tap & Die Co., Galt, Ont., resigned his position with that company on March 30th.

Technical Education Applied to Railroad Operation*

By Professor H. O. Keay **

A careful perusal of the contents of this paper will serve to show that a thorough grasp of the present day requirements of railroad transportation and operation has been taken by those entrusted with the training and equipment of those who will in the future be responsible for the development and progress of this important feature of Canada's agricultural, industrial and commercial life.

NUMEROUS people continue to be disturbed by the question as to whether railway service offers what may be really called a profession. A brief consideration of the importance of the part played by the railways in our national life may help to throw some light upon this point. Recent figures indicate that over 30 per cent. of the entire population of the North American Continent have a direct interest in the railways through their private deposits of money at banks investing in railway property; men actually engaged in the service, together with their dependent families, comprise 10 per cent. of the population; and the production of railway supplies involves fully 70 per cent. of our industrial activities. Assuredly, if the administration and control of the intricate machinery of this vast enterprise be not a profession, it is a thing which so far transcends the ordinary profession that it demands the finest training which may be within our power to provide. The happy-go-lucky days of railroading, picturesque though they may have been, are passing. Scientific method is more and more necessary with the decreasing margins of profit realized in the affairs of transportation in general. With a public alert and keen to reduce the price of transportation of every sort, and an army of employees who are equally enterprising in advancing the cost of such service, the railways are finding that the candle has been burning at both ends for so long a time that it is, in many instances, becoming extremely difficult to hold. Under these conditions the official who has the broadest view of the situation, who can weigh the saving in one department against the disadvantage in another resulting from a given policy, is more and more in demand.

Railway Educational Schemes.

It is felt in many quarters that the present process of promotion in some measure fails to give all that might be desired in breadth of training. The shell of departmental prejudice hardens with maturity, so the most favorable time to begin a broadening of view is early in the experience of the individual, when the mind is most receptive. A desire to furnish some means of providing a more adequate training of young men in the operating department is reflected in the various railway educational schemes which have been evolved on this continent and abroad.

The success or failure of any railway educational scheme rests largely, however, upon the manner in which it is woven into the practical fabric of the railway itself. If the student is left to wander at will into the maze of railway life and there attempts to square up his theory with what he finds, the results may fall short of our expectations. His practical training should be definite, and mingled as closely as vacation periods will permit with his university work. The university must be the place of method; the railway the place of practice; and each should complete itself in the other in a well balanced experience. To this end, arrangements have been made with the Canadian Pacific Railway whereby definite practical training is offered to a number of students in the Transportation and Mechanical Courses of the University who care to avail themselves of this privilege. Thus, the summer vacations and a period of two years after graduation may be utilized to give the student a broad practical railway experience, with a view to developing men for official positions.

The Transportation Course.

The summer training for both Transportation and Mechanical students is the same for the first two years; at the end of which time, students are required to make a decision as to whether they desire to adopt the Transportation or Mechanical Course. The work arranged for Transportation students is as follows:—

First Year (Vacation).—Three months as special apprentice at the railway shops.

Second Year (Vacation). — Three months as special apprentice at a round house.

Third Year (Vacation). — Three months in road service as an extra brakeman.

*Abstract of paper read before the Canadian Railway Club, Montreal.

**Of McGill University, Montreal.

After Graduation.—Three months in station service, three months in Stores Department, three months in Master Mechanic's Office, six months on track work, three months in Accounting Department, six months with Train Master.

In connection with this Transportation Course, the Grand Trunk Railway has under consideration an even more comprehensive scheme of practical training, incorporating some of the additional advantages of that of the Great Central Railway of England.

Railroad Official Opinions.

No educator is so blind as to be unaware of the fact that many a college man has failed to "make good" in railway work, and in the building up of this Transportation Course no pains have been spared to search out the common causes of failure, and so far as possible, to correct them. Perhaps the testimony of one or two eminently successful men will be of interest. In discussing this course recently a prominent Canadian railway official gave the following as his opinion:—

"The immediate trouble with the ordinary college graduate is that he has climbed to a higher plane of thought, from which he finds it difficult to descend again to the details of practical work. His breadth of view has unfolded visions undreamt of by the fellow submerged in the details, but the development of generalities and principles has given him a distaste for the necessary fundamental facts of a business from which he has been too far removed.

"Starting with three men of equal native ability—one in practical railway work, one in the ordinary college course, and the third in this Transportation Course, it is my opinion that the practical man will keep ahead of the man of ordinary college training, but that the one who has followed a course so balanced between the practical and the theoretical as the one described, will outdistance both of the others."

Mr. F. W. Taylor finds that lack of discipline in many of the colleges is responsible in part for some of the failures. He says: "During the four years that men are in college, they are under less discipline and are given greater liberty than they have ever had before or will ever have again." . . . . . and, further, "In facing this question, I would call attention to one class of young men who are almost universally imbued with an earnest, logical purpose; namely, those who, through necessity or otherwise, have come into close contact and direct competition with men working for a living. These young men acquire a truly earnest purpose. They see the reality of life, they have a strong foretaste of the struggle ahead of them, and they come to the university with a determination to get something practical from the college training which they can use later in their competition with men.

"I believe it is possible to so train young men that they will be useful to their employers almost from the day that they leave college, so that they will be reasonably satisfied with their new work instead of discontented; and to place them, upon graduating, one or two years nearer success than they now are. This can be accomplished by giving them an earnest purpose through six months' contact, early in their college life, with men working for a living; by rigidly prescribing a course of studies carefully and logically selected with some definite object in view; and by subjecting them to a discipline comparable with that adopted by the rest of the world."

Combination Theoretical and Practical Training.

In endeavoring to overcome the usual objections to the college graduate, it is felt that a number of points of advantage have been brought out. The subjects included in this course have been brought close to railway needs and problems. The four month vacation periods have been utilized to alternate the theoretical and practical work in as perfect a balance as circumstances will permit, to the end that the student is never long out of contact with serious actual work and the advantages which come from early competition with the wage earner. Here a respect for order and discipline is impressed indelibly, and the truth brought home that to ever hope to command, one must first learn to obey. It is expected that the graduate will ultimately specialize in one department or another, but our faith is founded on a breadth of training before any intense specialization, and at a time when this can be accomplished without humiliation or apparent retrogression.

The course is young—its first graduating class being in 1908, and its graduates are not a numerous body, yet among those who have followed out the practical training with their theoretical work are already numbered two locomotive foremen and two train masters.

The Ultimate Aim.

The ultimate aim of the Transportation Course is to produce sound men who can "think straight," who have learned the value of co-operation and team-work versus a selfish individual "record,"—who have the perspective to measure the saving in one department against the consequent loss in another,—in short, who represent not so much the genius as the well balanced man who can work steadily to the best advantage of the company and to himself. No less a product is due the railways of Canada, who have given to the University an enthusiastic encouragement and financial support so far unparalleled in the annals of industry.

EVOLUTION IN THE MACHINE SHOP.

In the good old days of machine shop work considerable time was wasted in placing large pieces of work in the various machines, says an exchange. As the iron and steel work increased in size it was necessary to keep building larger machines to finish up the heavy castings. Now it has become the fashion to take the tool to the work rather than to carry the work to the tool.

In the turbine shop of the General Electric Company at Schenectady, N.Y., one can daily see a powerful electric crane carrying along a drilling machine, or some other machine, and placing it carefully inside the casting for a modern 30,000 horse power steam turbine. When the work is finished the machine is taken away and another substituted.

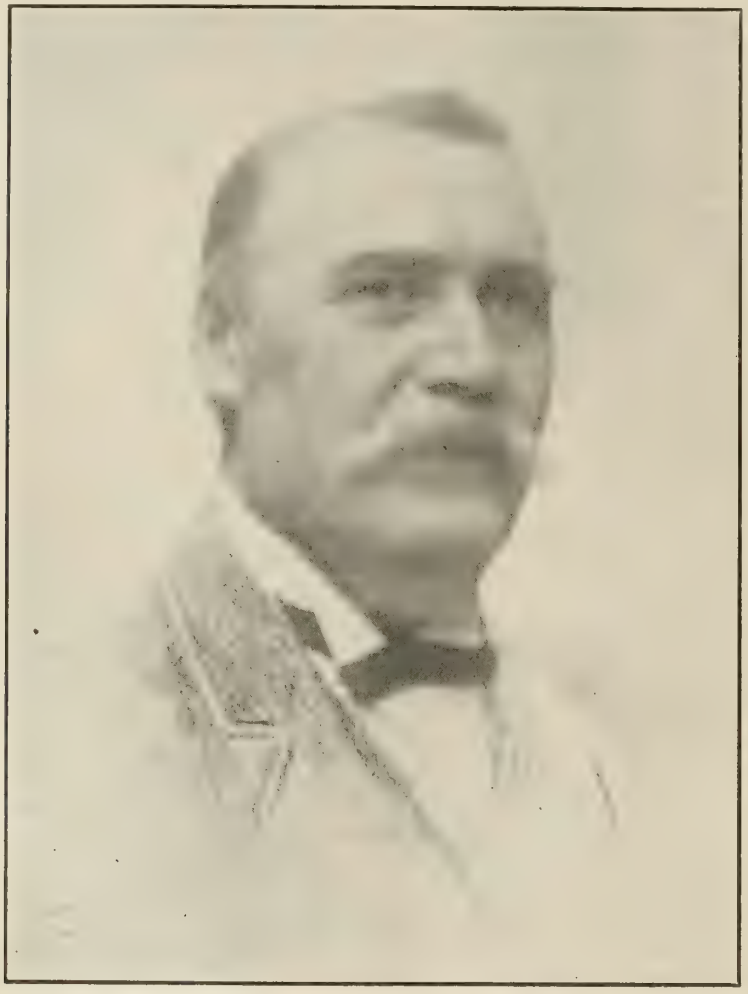
This change in machine shop practice is almost wholly due to the utilization of electricity and the flexibility of power which it permits. The machines are all driven by individual electric motors mounted securely on the frame and fed by a small armored cable which can be carried to any part of the shop. It is easier to lift and carry these small machines to the work than it would be to handle such mighty castings over and ever again.

CHANGE OF NAME.

It is proposed to change the name of the American Brass Founders' Association to the American Institute of Metals, and members have been called upon by W. M. Corse, the secretary, to vote upon such a change in the constitution. This is believed to be advisable on account of the fact that the name will indicate a much broader field. The present name indicates that the work of the society is confined to brass exclusively, and it is desired to increase the scope to all non-ferrous metallurgy. This has been done in England by the Institute of Metals and it is expected that the American transformed society will be conducted more along the lines of the English Association. The next meeting will be held in Buffalo in September and this change has been made on account of lack of facilities for holding the annual convention earlier in the year.

THE LATE MR. W. T. BROWN.

WE regret to have to record the death of Mr. W. T. Brown, one of Canada's prominent and successful sons in the realm of mechanical engineering; the unlooked-for event having taken place on February 9, at his home in Galt, Ont. On previous occasions due to periodical breaks in their ranks, we have been called upon to refer to the large part such men as the late John Dyer, Thomas Pringle, Walter Laurie, Edward Lamb and J. C. Weir have played in the development of mechanical engineering activities and successful undertakings, and to these must now be added the name of Mr. W. T. Brown, who for nearly a quarter of a century has been connected with the engineering department of the Goldie & McCulloch Co., Galt, Ont., during which long period he had won and retained the confidence and respect not only of his employers, but that of all with whom he came in contact in both a business and social capacity.



THE LATE W. T. BROWN, OF GOLDIE & McCULLOCH, LTD., GALT, ONT.

Mr. Brown was born in Toronto in the year 1846, but when quite young, moved with his parents to Bowmanville, where he served his apprenticeship with Meads & Son, founders and machinists. On completing same he returned to Toronto for a short time, after which he went to Oshawa, where he was a valued employe for a number of years of F. W. Glenn. It was in Oshawa that he met Miss Annie Davey, to whom he was married in 1867. They resided in Oshawa until 1874; leaving for Ottawa in that year when Mr. Brown became superintendent of the waterworks. In 1880 he moved to Cleveland, Ohio, where for two years he was superintendent in the machine shop of the Cleveland Rolling Mills. In 1882 he and a partner went into business in Carleton Place; which business was later moved to Dresden, In 1886 he disposed of his interest in the partnership and came to Hamilton where he was superintendent of the Beckett Engineering Co.'s works.

It was in the year 1889 that he accepted a position with the Goldie & McCulloch Co. of Galt, with which firm he remained until his death. During the first few years of his connection with the Goldie & McCulloch Co. he acted as traveling representative and superintendent of erection. He was later made their mechanical engineer, and for the last six years has acted as their estimating engineer. He left his desk on the eve of February 9, in his usual health, and in less than an hour had gone to his reward; his very sudden death being due to heart failure.

Mr. Brown was a true friend, a man of sterling integrity and greatly beloved by all who knew him.

PORT NELSON AS HUDSON BAY RAILWAY TERMINAL.

THAT Port Nelson shall be the terminus of the Hudson Bay Railway in preference to Fort Churchill is decided by the report of Chief Engineer J. Armstrong, in charge of the construction of the road, and of the surveys which have been in progress during the last two years to determine routes. This report, dated January 23rd last, was tabled in the Canadian House of Commons on March 4th by the Minister of Railways and Canals. In brief, Mr. Armstrong finds that while Fort Churchill has naturally the better harbor protection, it has an inadequate site available for railway termini; is open for only five months in the year, and involves a longer and more expensive route, with greater cost of annual maintenance. Port Nelson, on the other hand, has ample and easily utilized terminal sites, is open seven months in the year for navigation, and from the standpoint of ultimate utility is decidedly to be recommended. A comparison of routes shows that the distance from the Pas to Port Nelson is 418 miles, as compared with 498 to Churchill. The Port Nelson route has a gradient of only 4-10 of 1 per cent., and on an estimate of 3,000 trains per year could be operated, including all interest charges, for about 3,000,000 dols., or about half a million less than the Fort Churchill route.

As to the question of terminal sites at Port Nelson, it is interesting to note in view of the recent Order in Council giving Ontario the south side of the harbor mouth, that Mr. Armstrong declares suitable terminal sites are available on either side of the river. The cost of terminal development at Port Nelson, having in view the handling of from 60 to 70 million bushels of grain within sixty days, is estimated at 20,000,000 dols.

A comparison is given between the proposed route from Saskatoon to Port Nelson, across to Hanna Bay, and thence via the Quebec and Lake St. John Railway to Quebec, and the present route from Saskatoon to Fort William and Montreal via Parry Sound. The total length of the former route is 1,950 miles, of which 750 miles is water carriage; the total length of the latter is 1,950 miles, of which 680 miles is water carriage.

CANADIAN MACHINERY
AND MANUFACTURING NEWS

A monthly newspaper devoted to machinery and manufacturing interests, mechanical and electrical trades, the foundry, technical progress, construction and improvement, and to all users of power developed from steam, gas, electricity, compressed air and water in Canada.

METHODS AND DEVICES.

IT is hardly necessary, perhaps, for us to draw attention to the department of "Machine Shop Methods and Devices" in the present issue of Canadian Machinery, illustrating as it does in a marked and effective degree without egotism or "still life" portraiture "who's who?" "what's the reason and why," in matters pertaining to the progress and development of mechanical engineering and machine manufacturing practice.

The community of effort reflected in those pages is, needless to say, a source of more than passing pleasure to us, believing as we do that most men are "from Missouri" and want to know, not only what Jimmy Jones is accomplishing, but the manner and method adopted and employed. Vague generalities, which tell of wonderful results achieved, yet carefully avoid detailing the conditions and circumstances, are much like asking a hungry man to help himself to a meal by lapping the steam from a restaurant window. If we or you have something worth telling to others, let us do so to the fullest extent necessary and possible; realizing that fairy tales and smoking room stories belong to a class of literature somewhat distinct and remote from that devoted to mechanical engineering.

Our range of contributors in this issue includes all the provinces of the Dominion and some from England.

DOCTRINES OF SUCCESS.

IF we would judge by the prominence given to the achievements of individuals in the accumulation of material wealth and be guided into the belief that therein lies the true and only solution and attainment of success, then without much stretch of imagination or superiority of perception, it is a safe and reasonable conclusion to affirm that the already well packed battalions of desperados will continue to add recruits to their ranks. Fortunately for the individual, the business world, the community and the country, there exists a wealth of balanced brain able to discriminate between the real and mythical. Men of this latter stamp—we all know them, and you are without doubt one of the number—have and are attaining success daily, by achievement just as great and possibly more so than the majority of those so prominently idolised.

You hear and read of jobs which will command salaries of $50,000, $25,000, $10,000, $5,000, etc., per annum being impossible of filling, as the men to hold them down are not available. You scratch you head, do a little hard thinking; yes, even philosophize and arrive at the conclusion that no power or institution on earth will qualify a man to fill either one of them unless he be offered it and have an opportunity to make good. We are told that the ranks of mediocre men are bulging to the bursting, while those of the gifted and talented are yawning and gaping to be filled, yet it never seems to occur to the instigators of these wild and extravagant utterances that they are alone to blame for existing conditions. They lose sight of the fact that a large proportion of what are dubbed "mediocre" men, have attained the highest success in their sphere, and that only by systematically applied prejudice on the part of those higher up are they forbidden opportunity to rise.

With all the necessary deference to those who presume to speak of success as so many thousand dollars per annum of salary, or millions to their name in a bank book, let us say that the bulging of the "mediocre" ranks is largely due to real heroic success achieved and that the gaps in the other are more or less due to a distorted view of conditions, ignorantly or purposely chosen. Most men, yes, even "mediocre" men, possess the bump of common sense to a large degree, therefore, their conception of tall stories of salaries available is likely to be more or less uncomplimentary to the originators of the latter. There will always be those who have won success as measured by dollars; a few who have achieved the distinction of real success and dollar wealth in addition; but it may not be forgotten that the great majority must be content with real, naked and unadulterated obscure achievement.

How idle, even criminal, is it then to dangle impossible and meaningless doctrines around which, it is known full well, cannot be compassed The business man or manufacturer we are so prone to laud has been a success because of the accumulation of the combined successes of those who served him, and not to the extent some would have us believe, because of his own foresight and acumen. His success has been achieved by loyalty of the rank and file and just in proportion to his material recompense and theirs may his loyalty to them and real success be measured.

U. S. MACHINE TOOLS AND TARIFF REMOVAL.

NOT the least important projected legislation of recent times has been the proposal to remove the tariff on machine tools entering the United States. Naturally the home builders of these commodities resented being called upon to meet competition on a free import basis, and took steps to combat the measure and prevent it becoming law. British-made tools, even against a high tariff, find a market to some extent in the United States, and it would be a natural result, due to lower labor cost, and a free market, that a largely increased trade would materialize. Our view is that the possibility of a tariff removal on machine tools entering the United States is a remote contingency.

MACHINE SHOP METHODS AND DEVICES

Unique Ways of Doing Things in the Machine Shop. Readers' Opinions Concerning Shop Practice. Data for Machinists. Contributions paid for.

ONE WAY OUT.

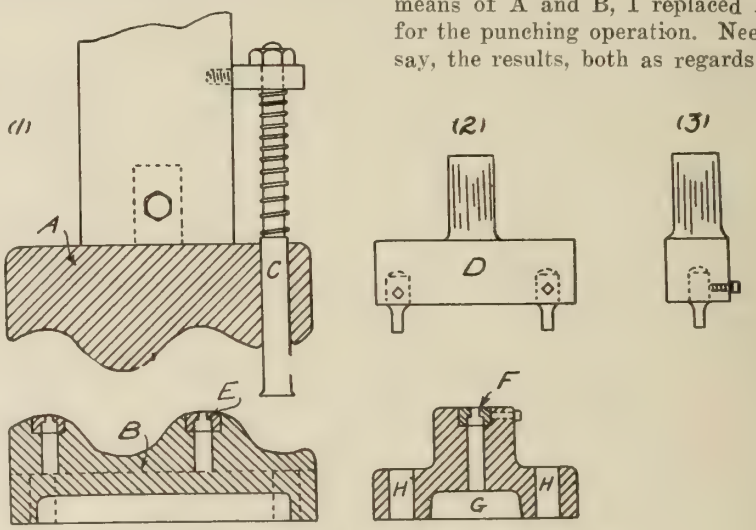
By Donald A. Hampson.

ABOUT noon, Walsh, the well driller, phoned that he was sending in a stem to be re-threaded and asked if he could have it done right off. I told him it would be started as soon as it arrived and thought no more of the job until it came in, for we often re-cut his worn and bruised threads. When that stem showed up, however, it was 9 feet long. Previously pieces of from 4 to 6 feet had been received, and even these were about 18 inches longer than we could take between center. It might, therefore, almost as well have been 18 feet too long; but having agreed to do the job, I could not back out. As I already had a mental conception of the expedient to be adopted, Walsh was called up, the situation explained, and his O.K. secured regarding the extra cost.

There were in the shop two lathes of 20 inches swing x 4 feet between centers and alike in all respects. They had passed their first youth and were used for rough work, so we didn't object to tearing them down for odd jobs. After removing the headstock of one and the tailstock of the other, the lathe A. (see drawing) was moved up against lathe B. Long parallels, one shown as P., were set on the ways on each side and held with heavy C-clamps. Below straps and a pair of long bolts between the legs tied the lathes together. Wedges were slipped under the feet of A. to level up. I put the carriage of A. in gear with the head of B. and had a coupling, C., made to join the lead screws.

In order to get the right taper, the lower part of the tailstock was entirely removed and the upper part mounted on parallels laid across the lathe, in which position it was clamped by a pair of 3-4 inch hook bolts, D., passing over the extended ends and secured below by straps across the bottom of the lathe bed. Owing to the limit of carriage travel, due to the parallels under tailstock and also to the big "set over" in getting the taper from 2 inches to 3 inches on the short length of thread, the regular tool post could not be used and an extension slide rest, R., was bolted to a wing of the carriage and held the thread tools. E. is a length of 2 x 4 inches to take the end thrust off the centers.

Though several men were employed all the afternoon getting this combination ready, the customer got off much easier than if the job had been sent to a distant shop; which proceeding would have involved transportation charges, his own men's time, and incidental delays. Fortunately for us, we had lots of help available and an unusually complete shop equipment to draw from.



Jig for Pressing and Punching Corrugated Sheets.

JIG FOR PRESSING AND PUNCHING CORRUGATED SHEETS.

By G. Barrett.

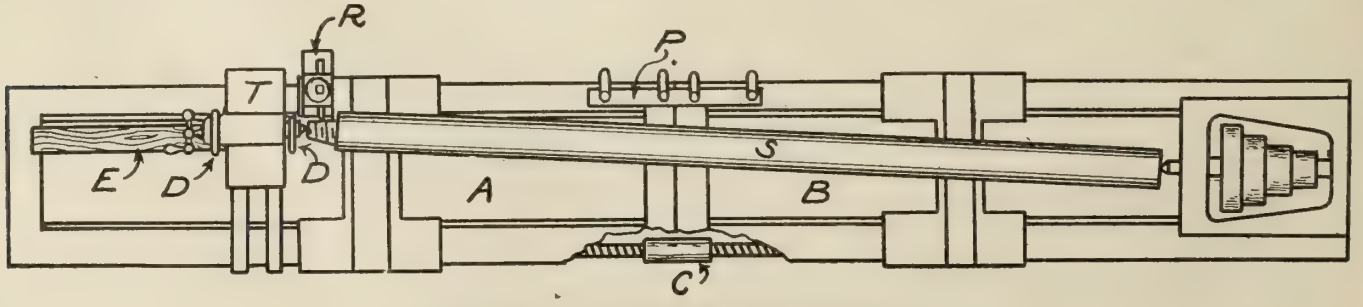
THERE is here described and illustrated a useful jig for pressing and punching corrugated sheets. As I had a large number of these to do, the jig A was made to press on the fixed block B. The rod C keeps the sheets until the press meets them, the spring giving the necessary tension. I used the block B also for punching by making extra steel dies and the punch D. The lower figure, No. 2, shows the side view of block B, which, it will be noted, is cored out at G to catch the punchings. Four holes H are for fastening down block B.

After pressing the bent sheets by means of A and B, I replaced A by D for the punching operation. Needless to say, the results, both as regards quality and quantity of performance, amply justified the outlay for jig equipment.

FITTING TAPER BOLTS.

By T.R.

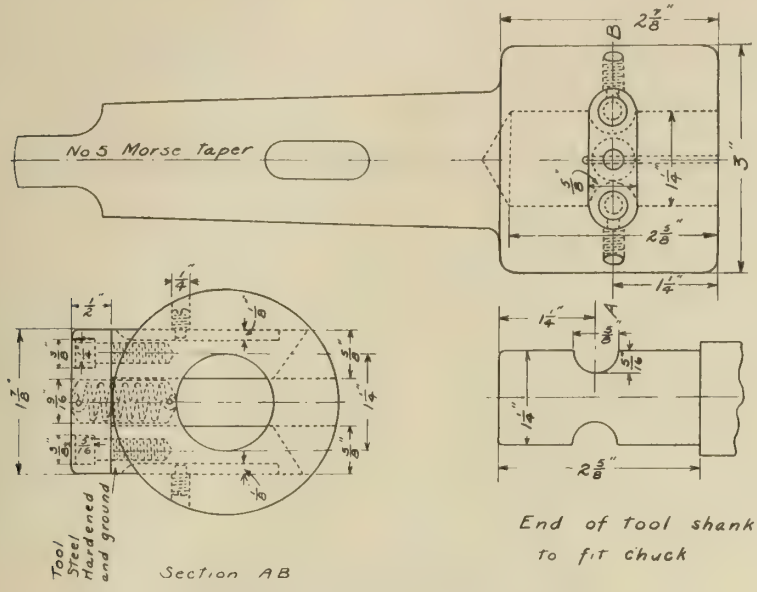
IT is an everyday job in a locomotive shop for machinists to make bolts for big ends, frames, etc., which have been previously broached-out; but it may happen that, while knowing the amount of taper:—1-16-inch per foot, the top and bottom edges are burred or chipped, thereby making it a matter of more or less chance if you strike the sizes accurately with calipers at the first trial. An



One Way Out—Re-threading a Well Drill Stem.

easy way out of the difficulty is as follows:—

Turn a long taper pin and polish it smooth; making the large end something in excess of the size of bolt you are called upon to provide, and the small end, something smaller than the bottom hole. To find the different sizes — chalk the whole length of your taper pin on opposite sides and insert into the hole. By first revolving the pin at the top and then at the bottom, you will get the desired sizes from the rubbings. If you now make allowances for driving the bolt home, much time and worry will have been saved, especially if you had to go far to test the taper and fit.



Special Chuck for Jig Work in Drill Press.

SPECIAL CHUCK.

THIS special chuck is used for jig work in a drill press, where a large variety and number of tools are required on the particular job in hand. The chuck will push down, pull up and turn anything within its range without fear of the tool dropping out; the latter contingency being impossible until the tool is released by the operator. This, however, he can do instantly, without the use of a wrench or other appliance.

The body, of machinery steel, is case-hardened on the tang to prevent battering. The tool shanks have two half-round slots milled across them, and two sliding grips in the chuck fit into these. The two sliding grips are connected by a bar of steel, so that both can be pulled out together. These are held in place by a spiral spring, with a dog pointed screw fitting into it. A key way is put into each grip so that it can only be pulled out far enough to release the tool; there is, therefore, no chance of stretching the spring beyond its limit of elasticity. The sliding grips are of tool steel, hardened, ground and closely fitted to the holes.

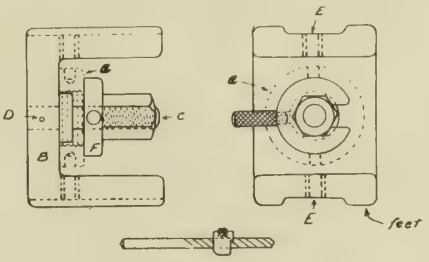


Fig. 3—Simple Drill Jig.

This chuck has driven a 3-inch 12 T. tap in cast iron, only one tap being used in the hole, and no marks were visible on the tap shank.

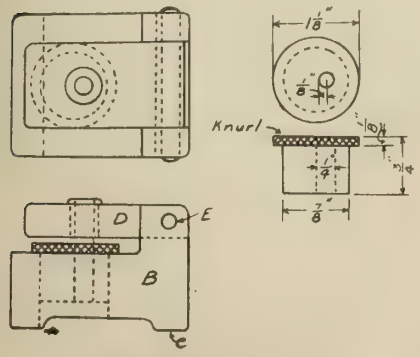

Fig. 1—Simple Drill Jig.

THREE SIMPLE DRILL JIGS.

By Chas. Hattenberger.

IT is agreed among foremen and toolmakers that a jig must be durably constructed, fool proof, and simple to operate, as the user is generally an unskilled man or boy. These features are all embodied in the jigs shown in Figs. 1, 2 and 3.

Fig. 1.—This jig was made for drilling the fitting seen on the right, which is a cam used for adjusting the spark on a gas engine. The pieces were first turned up in the lathe and cut off to the proper length. The ¼-inch hole had to be ⅛-inch off centre, and was drilled in the jig as shown. "B" is the body, with a ⅞-inch hole bored at right angles to the feet, "C." "D" is a hinged plate, which carries a hardened steel drill bushing. This bushing is located ⅛-inch beyond the centre of the hole in "B." The hinged plate is a working fit in a slot cut in "B" and swings on the tool steel pin "E" which is hardened and ground. The pin should fit tight in "B" and be a working fit in "D." To operate, insert the fitting and bring down the hinge "D." No screws or clamps are needed for fastening, as the hole drilled being off centre will not permit the cam to turn. The parts "D" and "B" are of soft steel. A cam is shown in the jig.

Fig. 2.—The bronze bushing shown requires to have a 9-64-inch hole drilled in it. To accomplish this rapidly and ensure interchangeability, the jig shown was made. The body part "A" was made of soft steel, and a portion of the base was milled away to form the feet "C." The drill bushing was placed in a plate "B" which was fastened to "A" by three ¼-inch fillister head screws. The bronze bushing was inserted in the opening "D," then placed against the stop pin "E," and fastened by the clamp "F," which is operated by the screw shown. A spring was placed under the clamp to hold it up when the screw was loosened.

Fig. 3.—This jig is used for drilling two 3-16-inch spanner holes in the 15-16-inch 14-thread collar shown by the dotted lines at "A." It consists of a channel shaped frame or body "B," each end having a portion cut away to form the feet. The centre bolt "C" is held in place by a ⅛-inch pin "D," which extends through the bolt. Two drill bushings "E" are pressed into the frame "B" and the washer "F" has a slot cut in one side which allows it to be rapidly removed without first undoing the nut. The size of the nut across the corners must be slightly smaller than the size of the hole through the collar at the root of the thread. A knurled handle is

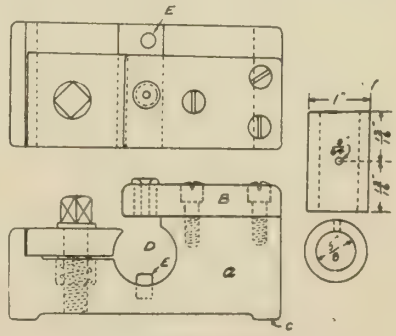

Fig. 2—Simple Drill Jig.

provided to remove the washer. To use the jig, slip the collar over the nut to the flange of the centre bolt. The diameter of this flange is .815 inches. The washer is next put in place and fastened by the nut. First drill one hole, then turn over and drill the other. The centre bolt and nut are pack hardened, and to insure the holes being of the same depth, use a drill with a stop collar as shown.

RADIAL PLANER TOOL CRITICISM.

By A. P.

THE reason for this letter is not that I wish to cast any reflection upon the writer of the article, "A Radial Planer Tool," which appeared in your February issue; rather is it to point out where the construction is incorrect, its weakness and undesirability for service. Being located several thousand miles away, I have not, of course, seen the apparatus in operation, at the same time, I venture to say that the tool did not and will not take even a decent cut without chattering or digging into the work. Further, to do planing of any kind with a tool holder such as it, only very light cuts can be taken, which in these days of high speed tool steels and keen competition cannot well be tolerated.

Figure 1 is a side elevation of tool and holder referred to, with the addition of part of the clapper box, for the purpose of facilitating the explanation of the defects, etc. It is well known that a tool under the action of cutting tends and actually does spring away from its work at about its point of support. Upon examination of Fig. 1 we see that the point of support is at A. Designating the cutting edge of tool as B, let us take A as centre and A B as radius and describe arc C D. By noting its direction, it is at once obvious that the tool moves in the path C D in the direction indicated, thereby doing its utmost to dig into the metal.

Fig. 2 is practically the same as Fig. 1, except that the revolving tool holder which carries the cutting tool is placed behind the shank instead of forward of it. Using the previous reasoning, we find by taking point A as centre, A B as radius and describing an arc C D, that the cutting tool not only tends to, but actually does clear itself, due to its spring under the weight of the cut. Further, when the shank springs back in this manner, it attains an additional elastic force or resilience which is most useful in overcoming such places on the casting as may be harder than others, not to mention the fact that the job when finished has a superior and workmanlike appearance. There is also the time saved in being able to get at it without fear.

After the foregoing explanation, I don't think it necessary for me to point out that the tool carried as shown in Fig. 2 and will stand up to its work for a longer period and at the same time be capable of taking heavier cuts.

LOCOMOTIVE SIDE RODS. FITTING KNUCKLE BUSHES AND BRASSES.

By T.R.

FITTING knuckle bushes and side rod brasses into new rods is a cinch, but when they have to be renewed on a locomotive that has seen its best days and there are no facilities, after the bush has been pressed home, to bore it out to size so that it makes an easy fit on the pin for running purposes, the operator is kept guessing.

You will find, after removing the old bushing, that the holes are "out of round," due to pounding; being as much as 1-32-inch in knuckle bushes and slightly more in side rod brasses, lengthways. As your lathe is not made to turn pins to suit distorted holes, you must take your size diagonally, leaving the calipers a shade tighter for a driving fit; then, by allowing a bare 1-32-inch for knuckle bushes and a full 1-32-inch for rod brasses over the pin sizes, you will have little trouble in securing a good fit, provided, of course, that your pins are o.k.

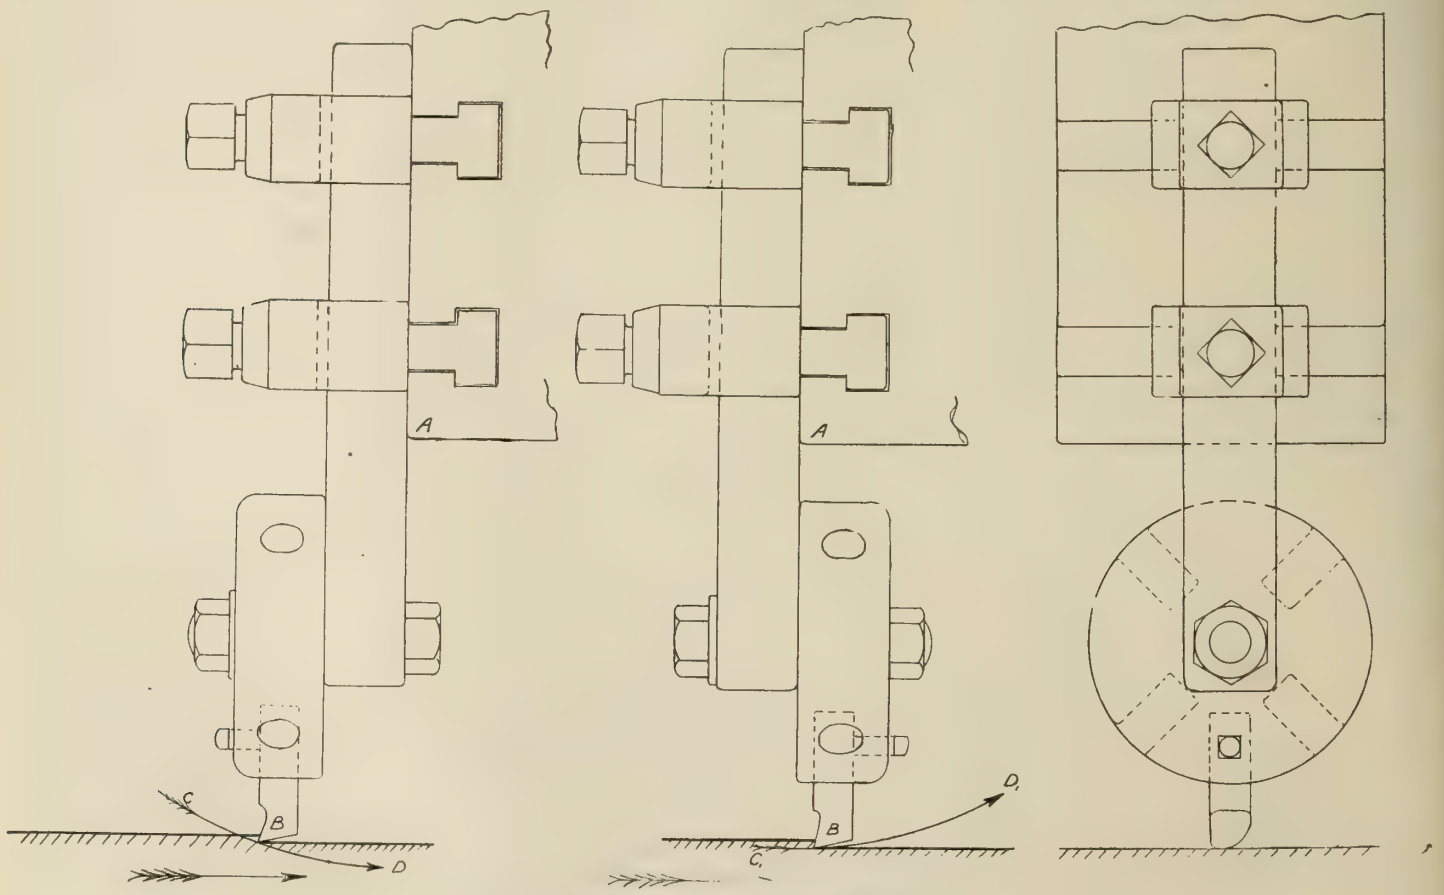

Fig. 1.—Radial Planer Tool Criticism. Fig. 2

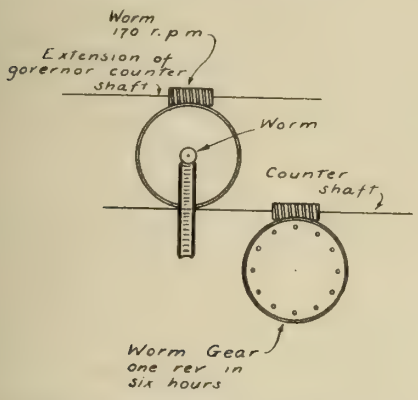
AUTOMATIC OPERATION OF HYDRO-ELECTRIC PLANT.

By W. A. P.

A RATHER ingenious device was constructed by the attendant employed to operate a miniature hydro-electric plant which supplied current to the buildings and grounds of a small summer institution.

A worm, which operated a train of worm gears and worms, was keyed on an extension of the shaft carrying the small governor pulley. The speed was reduced in this train from 170 r.p.m., the speed at which the first worm ran, to the remarkably slow speed of one revolution in six hours. The last gear in the train was this slow revolving link. About three-quarters of an inch from the outside of the rim of this gear, a series of twelve small holes was drilled, and a pin made which, when inserted in any



Automatic Operation of Hydro-electric Plant.

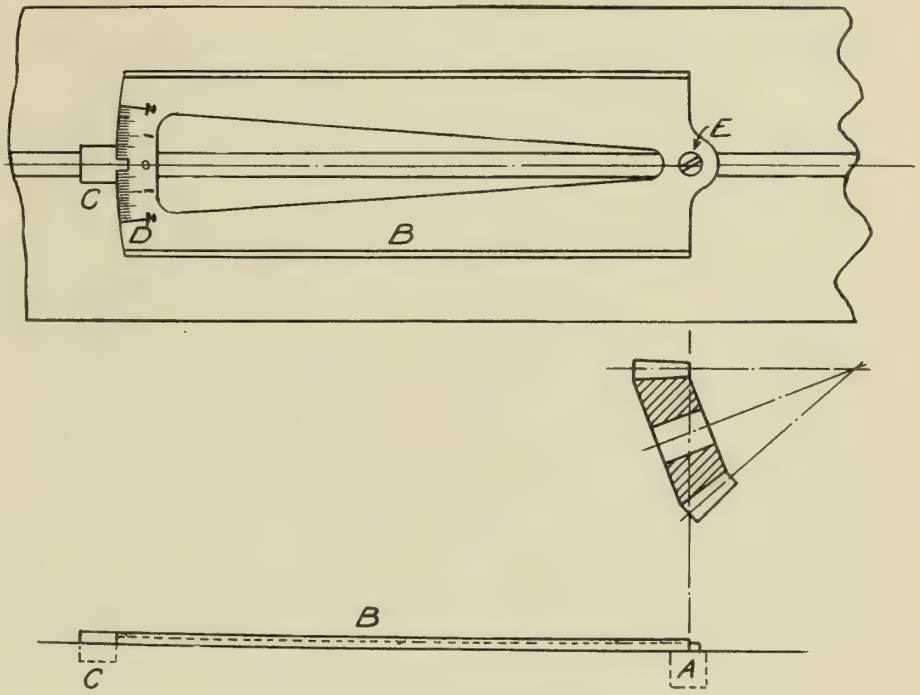
one of these holes, would at a given point in its revolution release a dog. This dog caused a small shelf to collapse and a weight resting on the shelf, had in consequence to be supported by a cotton rope tied to it and connected with a lever through a small pulley.

The sudden force thus imparted to the lever engaged a clutch which slid along a revolving shaft on a feather key, and this in turn set in motion the gate closing mechanism. The gate when closed was prevented from further motion by a positive stop. The timing was extremely simple. There were twelve holes in the rim. One revolution occupied six hours, therefore, if the dog were released at a given moment, and the pin immediately inserted in the next hole it would be exactly one half hour before the dog were again released. The plant could, therefore, be automatically closed down at the end of any half hour period, up to six hours.

CUTTING BEVEL GEARS.

By J. A. Wright.

THE following description of an attachment for cutting bevel gears may prove of interest to some of my fellow readers who have similar jobs perform. Referring to the cut, A is a block made to fit the slot in the miller table, and having that portion, which projects above the table, turned circular. B is a plate made to fit the head of the miller, allowing the latter to slide into any desired position. C is another block made to fit the table slot, having its upper face scribed with a centre line. D is a graduated arc on the back end of B, and E a hole reamed to fit the turned portion of A. The line F indicates the front end of the teeth to be cut. The universal head is set on the plate B, so that the line F coincides with the centre of E; the centre of the cut at F will then revolve as on a dead centre, requiring



Attachment for Cutting Bevel Gears.

no side adjustment of the table, if the cutter is of correct size.

Suppose the distance from the centre of E to edge of scale D is 20 inches and that we have to cut a tooth 2 inches long, from each side of which .06 inch has to be removed. To do this, the table B will be swung over about the centre E, until the scale D reads .6 inch, right and left alternately for the two cuts. Rule: Divide the distance in inches from E to D by the length of the tooth in inches, then multiply the amount to be removed from each side of tooth by the quotient thus obtained. The product is the amount the table must be swung over each way at D. The scale is graduated (full size) in inches and tenths of an inch.

After the two cuts have been made, the operator can considerably reduce the amount of subsequent filing necessary by running in sufficiently far a cutter of correct pitch for the small end of tooth, to show the true shape and form a guide for finishing.

EVERY DAY EXPERIENCES.

By H. A. W. Picton.

A MACHINIST'S duties are as a general rule more or less varied, especially when employed in smaller shops whose product is not standardized to the same degree as that of the larger shops. This varied nature of the work presents a great opportunity for men to pick up kinks and develop original ideas. A great many of these bits of knowledge, stolen as it were from the books of experience, may prove very interesting to our readers who pursue similar vocations.

Tool Grinding.

In a shop where there were several lathes with long beds, on which shafting was often turned, there happened to be one of these machines which was rapidly nearing the state where its usefulness was at an end. A "new" hand had been taken on and he was, of course, put on the old shaky machine. The "new" hand, however, was a man of experience and was not a little proud of some of the records he had established in other shops, for rapidly and accurately doing work. He realized the disadvantage under which he was laboring and this made him all the more keen to show his mettle. His past successes he could always trace back to one cause—namely, he was an expert in the art of grinding tools. He, therefore, carefully ground his tool, shifted the belt up one more speed, got started, and without the least appearance of chattering, the tool

continued to cut out the little curly pieces of steel.

The "new" operator held his own with the others, and the foreman, knowing the condition of the old lathe, was greatly surprised and decided to keep an eye open for developments. Pieces that usually caused a great deal of annoyance because they always persisted in chattering, were machined satisfactorily, and if on occasion a casting commenced to chatter, the speed was instantly reduced, the two spindle bearings tightened and the feed made less coarse. Then when the difficult surface was finished it was left without trace of chatter marks.

There is really always a reason for chattering, our friend says, and the commoner causes are the following:—

Causes of Chattering.

The spindle upon which the cone pulley is mounted may be loose in its bearings, the cutting speed may be excessive, the tail stock may have moved, due to a larger end thrust than usual, or if the saddle was allowed to bump into it, thus loosening of the mandrel between centres. Again the tool may have too course a feed or it may not be properly ground. The cutting point of a round-nose tool should not be too blunt and thus have too wide a cutting edge; also the clearance must be sufficient. When these are correct it is quite appreciable because the metal peels off in symmetrical curls, quickly and quietly. If tool holders are used it is not good practice to fasten the tool in too closely. Always leave the tool out far enough to allow the chip of metal to curl undisturbed. It is also bad practice to allow the tool to be fastened out too far. The overhang of the holder, also, should be reduced to a minimum, as this may sometimes cause chattering. Thus it is seen nearly all the causes of chattering arise from sources which are easily removed by a wide-awake machinist, except when caused by a badly ground tool. However, sometimes work will chatter in one place only, due generally to the method of driving. A dog fastened to a mandrel by means of a set screw sometimes causes chattering. It is often removed by placing a piece of cotton waste in the slot in the face plate of the lathe, in which the crooked tail of the dog is placed.

When facing a hub of a gear or pulley and you wish to lock the saddle of the lathe, it is usually accomplished by locking the nut in the lead screw of the lathe. Now, if the lathe is used a great deal, there is bound to be a little lost motion or back-lash here and to overcome this, it is always wise to throw in the nut when the tool is a short distance from the work and pull it up to the work by giving the gear on the end of the lead screw a turn or so by the hand. Then, when the tool is fed into the metal by the cross feed, it will face the hub squarely, which would not be the case if there were any lost motion to be taken up. Another little factor comes up for consideration here. With a round nose tool, a fillet will be left around the circumference of the bore. This is usually removed with a diamond pointed tool. Great care should be taken to avoid scoring the mandrel, as this is extremely bad practice. Some shops, however, have all their standard sizes case-hardened, and injury to the point of the tool will result before the mandrel is marked.

AN APPRECIATION.

Pleased find enclosed three articles for your "Machine Shop Methods and Devices" department; if those are suitable you may have more. I can assure you that this section of your paper is doing a great work among the boys by fostering discussion and teaching them how to plan and perform their work intelligently; therefore, economically and expeditionsly; concerning which, otherwise, they would be ignorant. Wishing your journal every success — R. T. J. R., Sutherland, Sask.

Speaking of cross feeding calls to mind a means by which a compound rest on a large lathe was operated by power. On the end of the spindle, outside the bearing that was remote from the face plate, an eccentric whose eccentricity could be varied, was placed. To this was attached a long rod; the other end being attached to an arm fastened to a small shaft on the wall behind the lathe. As the lathe revolved, the eccentric, through the rod and arm on the shaft, caused this shaft to oscillate. Several other arms were fastened to this shaft by set screws, at various intervals along its length. To any one of these arms a small chain was attached by means of a hook, and several holes drilled in that end of the arm distant from the shaft. The other end of the chain was fastened to a handle which operated a ratchet on the end of the feed screw. In this way the tool was fed into the work. The usefulness of this apparatus was, that it would operate the rest at any desired angle, and was quite easily adjusted. In fact, there were three different places at which the amount of the feed could be regulated. Firstly, adjustment was at the eccentric. It's eccentricity could be varied, and, thus, the shaft could be made to oscillate through a greater or less portion of a revolution. Secondly, the little hook could be inserted in any one of several holes in the arm projecting from the shaft, and where the chain was fastened to the ratchet handle, there was formed the third adjustment. The ring on the end of the chain was slipped into a hook which was in a collar that could be moved close to the ratchet or as far distant from it as the length of the handle would permit.

This simple arrangement costs but a mere pittance and can be fitted to almost any lathe, yet the results accomplished are quite as uniform as if the feed screw had a constant motion instead of an intermittent one.

Every machinist has his own experiences and has made his own little discoveries; it is to be hoped, therefore, that the foregoing few observations may lead a number of Canadian Machinery readers to tell others of them.

FORMULA FOR TURNING TAPER WORK.

By T.R.

MUCH time is wasted in a machine shop, which might otherwise be saved, because of the lack of a little elementary knowledge on the part of many first-class operators. For instance, the turning or boring of a long taper.

Assuming the former, with a length of 6 inches and a reduction from 12 to 7 inches. Let D equal the large diameter, d, equal the small diameter, and L equal the length. Then $\frac{D-d}{2 \times L} = \frac{12-7}{2 \times 6} = \frac{5}{12}$, which, if you have a machinist's book of tables and turn to those for tangents, you will find that 5-12 or .416, works out practically to 22½ degrees.

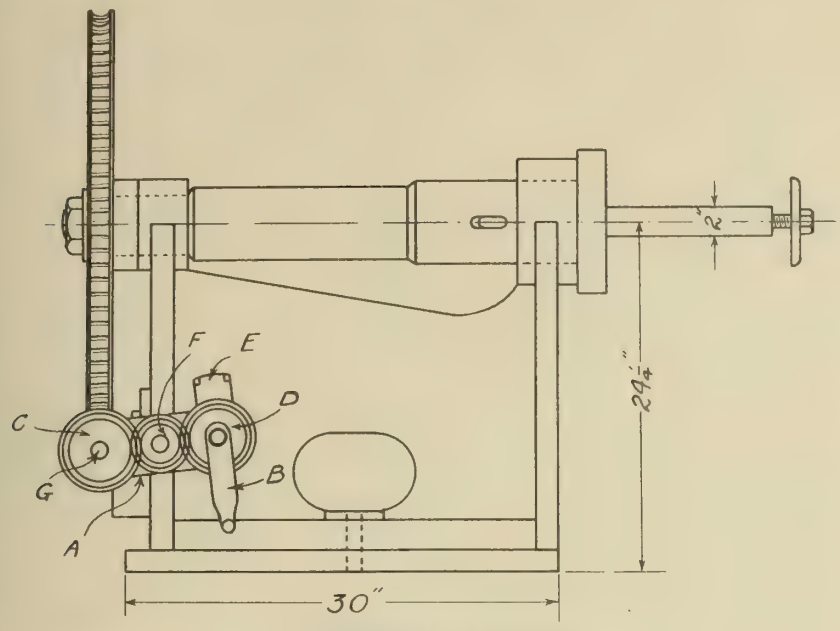
GEAR CUTTING ON A PLANER.

By Wilson Herbert.

IN our small machine shop it was quite a common practice to cut spur gears from machined blanks on a planer. This operation was accomplished with the assistance of a "dividing head," a sketch of which accompanies this article. The shaft, upon one end of which is mounted the worm wheel, is supported by two cast iron bearings in the frame. The mandrel in the other end has a tapered shank which fits into the shaft; and is securely held there by a drift. Thus, the mandrel is easily removed and different sizes made available.

The blank gear to be cut is placed on the mandrel and held against the solid shaft collar by means of a cap screw which screws into the end of the man-

drel and holds a washer against the hub of the gear blank. The worm gear is of cast iron, 180 teeth and ½ inch pitch; the worm being 2½ inches diam. by 3 inches long, and dipping into an oil well, as shown. This worm is keyed on a shaft which extends through brackets on



Cutting Gears on a Planer.

either side of the frame. Both ends of this shaft, are threaded for a three-quarter inch nut.

The remainder of the projecting portion is finished to 1 inch diam. and a small ¼ inch keyway cut in it. Upon this is mounted a small spur gear C. Another small gear D, is attached to the bracket A, and to the pin upon which it is mounted, a small hand crank B, is connected. These two gears are meshed, and the nuts tightened in the bracket. Every time the crank is vertical it will slip into a small pocket E, unless prevented from so doing by the operator. Under some conditions, it is found advantageous to insert a small idler F, between these two spur gears. This, however, interferes in no way with the operation of the machine, only serving to reverse the motion of the worm, and as our prime mover is the hand crank, it is simply a matter of reversing its motion.

Suppose it is desired to cut 29 teeth in a spur gear blank. Let us put the little spur gear having 29 teeth, upon the end of the worm shaft G, and on the pin to which the hand crank B is attached. let us place a 60-tooth spur gear which will mesh either directly or through an idler with the 29-tooth gear. Now, one revolution of the worm gear is accomplished by 180 revolution of the worm. This causes the 29-tooth spur gear to make 180 revolutions to bring (180×29) teeth into mesh with the 60-tooth gear. The number of revolutions the 60-tooth gear would make is (180×29)÷60, which is (3×29). Thus, it is easily seen that 3 revolutions of the hand crank (3 revolutions of the 60-tooth gear) cause the worm gear to make 1-29 of a revolution, therefore the mandrel makes 1-29 of a revolution.

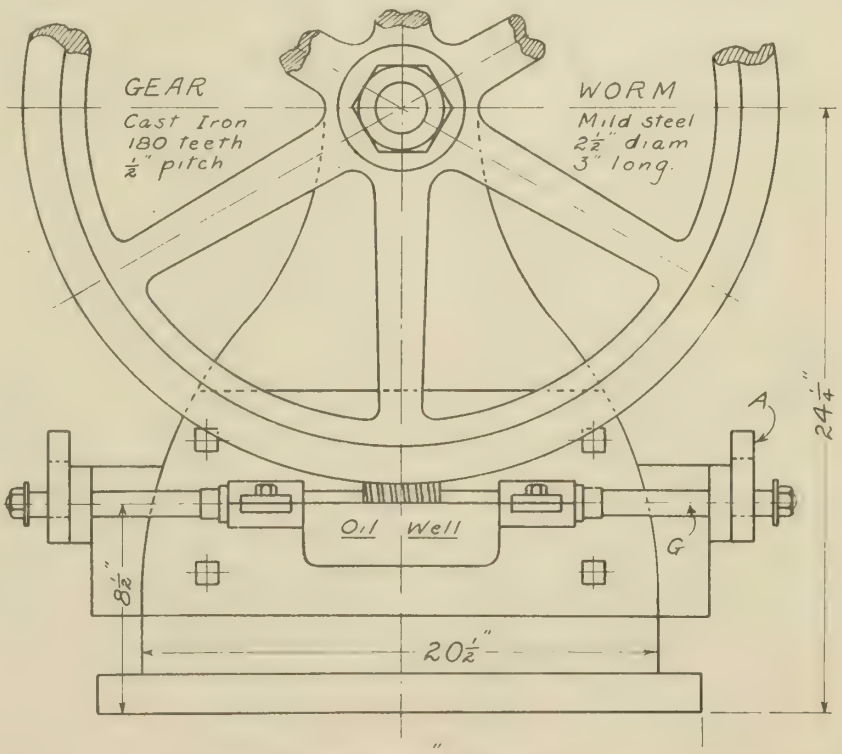
Operating Process, Spur Gears.

To cut a spur gear blank the dividing head must be clamped to the planer table with the axis of the shaft parallel to the direction of motion of the table. The gear blank to be cut must be placed on the mandrel and the set screw securely tightened. We have, of course, assumed that the bore of the gear blank corresponds to the size of the mandrel in the dividing head. If it does not, why a proper mandrel must be inserted or if a mandrel the required size is not available, it is an easy matter to make a couple of collars to fit over a smaller mandrel.

The first slot is usually cut with a square-nose tool whose corners are ground off to allow for a fillet at the bottom of the teeth. The width of this tool is of course governed by the pitch of tooth to be cut and can be determined from a little zinc templet which has three full size accurately shaped teeth filed in it. The limit of the space between the bottom of the teeth should not be slotted the first time because it is necessary that the finishing tool have a cut right to the bottom of the tooth. It is usual to feed in this tool horizontally.

Care must be exercised just here. Firstly, particular notice must be given to the clearance of the tool. Secondly, the little block in which are the four studs which hold the tool, should be in a horizontal position and the little pin on which it "locks" should be vertical. If these precautions be not attended to, and the tool should seize in a partially completed slot on the return stroke of the planer, the tool will tend to turn the gear blank slightly, with the result, that, when the tool enters the metal on the next cutting stroke it will cut the slot wider and, therefore cause trouble.

It is also good practice to have the tool long enough to extend through the block and to have a small spiral spring placed behind it to keep the block in its



Cutting Gears on a Planer.

position, because gravity does not avail, as it would if the block were vertical and rocked on a horizontal pin. When the blank has the required number of slots planed, one of the finishing tools is inserted, the cutting edge of this being ground to correspond to the curve on the zinc templet. If the circular pitch is large, it is perhaps wise to shape the tooth down to the pitch line only. When the foregoing operations are completed, the little index gears, hand crank and tool are removed to the other side of the dividing head, and the other side of the tooth face finished. The tooth is now finished down to the pitch line. The bottom half or flanks of the teeth are finished in the same way, the tools being ground so that their cutting edges correspond to the curve on the templet.

Operating Process Bevel Gears.

This method has also been employed to cut bevel gears when it was necessary to get them out with the greatest possible despatch. The gear blanks are machined as usual, but on the blanks two circles are scratched at each end of the teeth. These circles represent the whole depth and pitch circles for the large and small ends of the teeth. Here, we place the gear on the mandrel, small end towards the dividing head, and place the latter on the planer table so that when the planer has cut the slot the whole depth, it will be down to the whole depth circles at both ends of the teeth.

There are several ways of easily placing the dividing head at the proper angle. Two commonly practiced are:—First, set the head at approximately the angle, very close to the planer crosshead. Place one arm of a carpenter's square along the planed ways of the cross head and the other arm along the face of the gear blanks, so as to touch only at the extreme diameter of the latter. With inside calipers measure the distance to the whole depth circle at large end. Change the angle of the dividing head until the distance to the whole depth

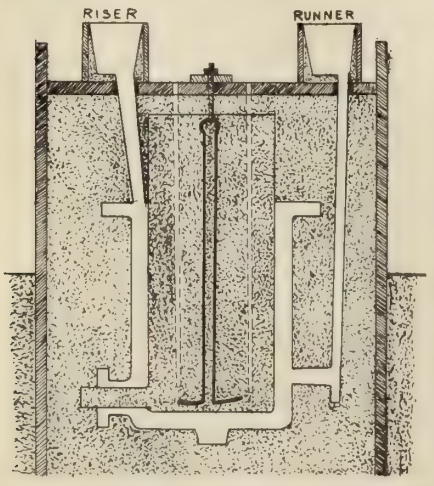


Fig. 3—Molding small cylinder in green sand.

circle at the small end is exactly the same; then the head is set.

The other method is somewhat easier although it requires great care to set the head accurately. From the blue print of the gear to be cut, get the angle on a bevel by placing one arm of the bevel parallel with the axis of the bore of the gear, and the other along the line of the

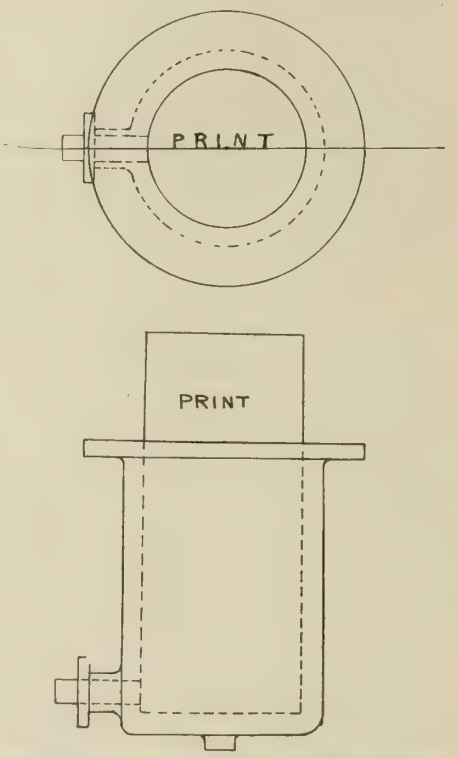

Fig. 1—Molding small cylinder in green sand.

bottom of the teeth. This must be an acute angle. Place one arm of the bevel parallel with the edge of the planer table, and parallel with the other arm set that edge of the dividing head which is parallel to the axis of the mandrel. When the head is set the slotting tool is inserted and cutting commenced.

The size and shape of this tool is governed entirely by the profiles of the small ends of the teeth. When the blank is slotted, the angle of the "head" is slightly changed so that the point of the tool, when fed down to the pitch circle at the large end, will be only down to the pitch circle at the small end when it reaches that end of the cut. The cutting edge of this tool has to be very carefully ground and great care taken with the clearance, to secure a smooth surface. Both sides of the tooth faces are finished as in a spur gear.

To cut the flanks, or that portion of the teeth below the pitch line, we must alter the position of the head, by placing it at the same angle as when the first slots were planed. The finishing cuts are taken as already explained. There is one point, however, to be noted. The fillet in the bottom of the tooth will be uniform, and its size is governed by the pitch of the tooth. Thus, it must not be larger than that which is allowable at the small end of the tooth.

Practical Considerations.

There are one or two points which come up in practice that one would do well to consider. In spur gears, the cutting edge of the tool should be on a height corresponding to the height that the axis of the bore is above the table. In bevel gears, when cutting the faces, the tool should be very slightly below this to insure the points of the teeth not being over size, and, thus, when in use, assuming an undue portion of the load. The tool when cutting the flanks should also be slightly above in order to give the tooth all the strength possible at the root.

With care, an approximately accurate gear may be cut if the face of the gear is not too great, and if the face exceeds certain limits, the number of cuts across the face may be increased. Three cuts, however, is a limit, as at best, the gears, being more or less only approximately cut, cannot be marketed as the perfect article.

MOLDING A SMALL CYLINDER IN GREEN SAND.

By John H. Eastham.

THE small cylinder shown at Fig. 1 whilst of exceptionally plain design, gave trouble in the machine shop as a result of being cast horizontally. Hard spots developed round the chaplets, which were necessary on account of the casting being open at one end only. In addition, the bore, whilst fairly clean, proved to be one-eighth of an inch out of centre at the closed end.

In view of these defects the foreman decided to cast future pieces vertically, without studs or chaplets of any kind. The method of molding the cylinder and securing the core was as follows:—One-half of the pattern was rammed-up on a board and turned over in the usual way, provision being made in the flask at the coreprint end for a runner, riser and hook bolt to pass through, the latter to act as a suspender for the core. An iron

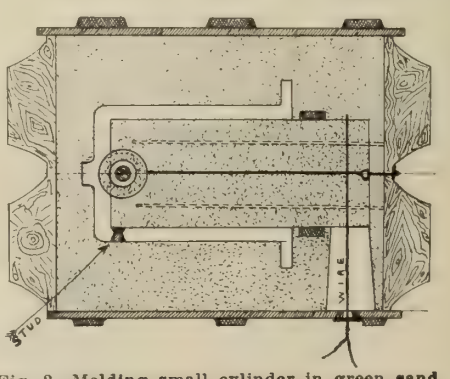

Fig. 2—Molding small cylinder in green sand.

bearing plate was rammed-up on the coreprint to prevent the possibility of a crush when placing core in position. The parting being made, cope rammed-up, and both half patterns drawn, the mold received the necessary finishing and blackening. A spool-shaped stud of correct depth was next placed as shown at Fig. 2, and a hole dug in the coreprint down to the bottom board.

The core was now placed in position, a length of flexible strong wire being bent over the print and passed down at each side through the board and twisted securely round a bar. The hook bolt was next looped around the eye in the end of the core iron, and bolted tightly to the end of the flask, the core being thus made practically immovable.

The stud was next removed, the cope lifted on and clamped, the mold turned-up into a pit, and rammed round to about two-thirds the depth of the casting. This was to prevent any strain or risk of a runout.

Fig. 3, of the mold ready for pouring, is self-explanatory, and shows the hook bolt arrangement, also the methods of gating and rising. The use of a good quality iron, poured at a high temperature, combined with the above safeguards gave excellent results, whilst the absence of chaplets prevented the risk of leakage so often shown in similar cases.

Mechanical Drawing and Sketching for Machinists

By B. P.

A Series of Progressive Lessons Designed to Familiarize Engineers With the Use of the Apparatus Necessary to Make Simple Drawings, to Encourage Them to Realize How Important a Factor it is of Their Equipment, as Well as Being a Profitable Pastime.

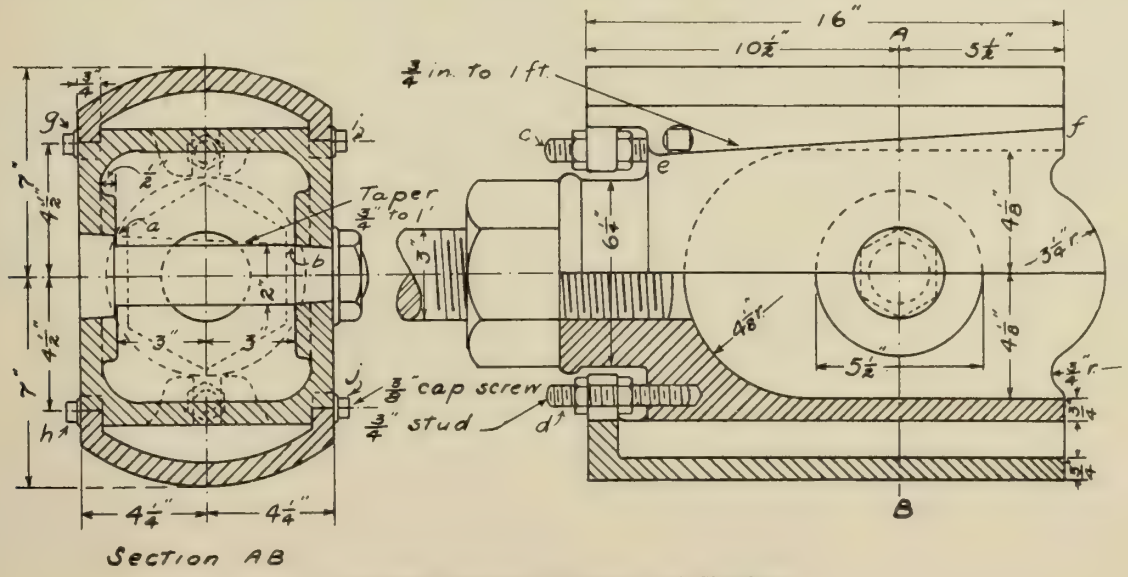
WITH this lesson we conclude our course in drawing, which has extended over a period of fourteen months. Thus, many of these ideas and suggestions will not only refer to the drawing of the crosshead, herewith, but in a general way to all drawings.

Crosshead Drawing.

This crosshead is taken from a high speed piston valve, steam engine, and was selected because of its extreme simplicity, although, at a first glance, it may look rather complicated. Several dimensions are, again, purposely omitted, to allow the student to develop his ingenuity and fill in. When proceeding with the drawing, it will readily be seen how many dimensions are required to make it complete. There are but two views: a side and end elevation. It is sometimes necessary to have a plan view, but in this case nothing would be gained by the addition of the latter. The side elevation shows the lower half of the cross head in section, while the entire end elevation is a section through the centre of the wrist pin. These two views show every detail of construction.

To start this example, it is necessary to first draw our centre lines. The wrist pin is the base about which the crosshead is constructed, and thus it is naturally the part to which we next devote attention. Let us place it in the side elevation first; projecting it afterwards over to the end elevation. The outside outline of the crosshead in this view is next filled in and projected across to the side elevation. Some lines are a great deal more readily obtained on one view than on another, and, with practice, the student will soon be able to see just where certain irregular outlines and points are found with the least labor. Having found them on one view, it is a simple matter of projection to locate them on the others; two or three views being, thereby, constructed simultaneously. When this method of attack is followed, a rather complicated drawing will soon be completed, and the student will often wonder why it is that some mechanics have difficulty in making a drawing from a free hand sketch obtained in the shop. Further, it makes him able to understand more complicated drawings quite readily.

Originality is a great asset in this work, some possessing it to a greater degree than others, but the ability to illustrate thoroughly any particular machine or part of it with the fewest number of views, cross sections and detail drawing is what every mechanic and prospective draughtsman should cultivate, even before speed is considered. Accuracy is another important matter, and too great attention cannot be paid to it especially in drawings and tracings of new machines. In completing the drawing of this crosshead, there is really no comment to make. Each difficulty, if



Crosshead—Mechanical Drawing and Sketching.

approached in the proper manner, will disappear, and in a remarkably short time, the drawing will be complete.

The wrist pin, as will be noticed, is tapered at both ends. The taper is three-quarters of an inch in one foot on the diameter. The pin is only turned tapering where it fits in the metal of the crosshead frame. However, both portions have been turned at one setting, and are parts of the same cone as is indicated by the dotted line from "a" to "b." The method of taking up the wear is that usually employed; two studs of ¾-inch dia. machinery steel being placed in the body of the crosshead as shown at "c" and "d" respectively. The top and bottom pieces are fitted to the body along inclined ways, as shown through "e f." A small lug is cast on each end of these shoes, and the steel stud enters an open slot in this lug. Two lock nuts, one on either side of this lug, adjust these shoes. Four little ⅜-inch cap screws, "g, h, i, j," respectively, pass through inclined slots in the shoes to the body, and hold the two together. The other details of the construction are self evident.

Concluding General Suggestions.

Before concluding, perhaps a few general suggestions that the student might do well to always bear in mind, would not be out of place. Dimension all drawings thoroughly. Very little can be said about the best methods of accomplishing this, as drawings are of such a varied nature. Try to arrange all dimensions in conspicuous places, and when it is necessary to subdivide them into several smaller units, place the smaller ones all in a single line nearer the outline than the over-all figure. Do not repeat dimensions on the same or different views unless for some special reason, and never allow your dimensions to be of such a nature that it would entail calculation or figuring on the part of the machinist. He is much more apt to make an error than you. Place the arrow-heads so that there will be absolutely no room for doubt as to what they refer. Make all dimension and limiting lines considerably thinner than the outline, but yet distinct. This also applies to centre lines, which should never be used as dimension lines. Instead of repeating a series of sizes, such as a number of bolt pitches, dimension two or three spaces and fill in the remainder as follows: Seven spaces at 3-inch each = 21 inches. When a fraction is used, always place the numerator directly above the denominator, and have them separated by a horizontal line. This prevents any chance of its being misread after the drawing has been in service for some time.

There is a limit beyond which dimensions should not be expressed entirely in inches. Each shop has its own limit, which varies from 24 to 100 inches. If a dimension is expressed in feet and inches, always make a liberal dash between the two sets of units, as 11 ft.—4½ in., otherwise it might be mistaken for 114½ in. When a dimension is an even number of feet always express as 17 ft.—0 in., to prevent mistakes from creeping in. In tracings from which blue prints are to be made, all lines should be made somewhat thicker to ensure good copies. When a drawing does not show up well, it is good practice to shade it. Make all similar lines of uniform thickness.

If a note on a drawing will explain a detail as well or better than a detail sketch, do not hesitate to use the note. Put yourself in the place of the man who is to work from your drawing.

It is a good plan to always place the title and necessary date in the same place on every drawing. The lower right hand corner will be found quite as convenient as any. Always use a convenient scale, and do not fail to have it plainly and prominently marked. Your choice should be the largest possible while keeping the drawing within reasonable limits. A hard pencil, kept well and properly pointed, should always be used.

A great many rules can be quoted, but cases will arise wherein the observance will be more satisfactory in the breach. We can only advise, therefore, a student to exercise his own common sense and originality, and in the measure that he does this his success will be assured. Suppose it is required to represent an engine connecting rod, and we wish our drawing to be not more than 24 inches long. For an assembled view of a large connecting rod, we should be required to use an extremely small scale, the details would be hard to represent and the drawing would be more or less unsatisfactory. To better represent this rod, make a detail drawing of each end to a comparatively large scale, and an another portion of your sheet make an assembled drawing sufficiently large to supply all details which may not be shown in the views of the two ends.

When a cross section is shown, if there exists more than one metal, the hatching should make this conspicuous. Conventional representations of screws and other details more or less difficult to represent, should always be resorted to and an explanatory note placed upon the drawing, if necessary.

With these ideas we hope the student may not only be able to intelligently understand a shop drawing, but with a little practice be able to make one himself.

ASSOCIATION FOR INTERNATIONAL EXCHANGE OF STUDENTS.

This association, which has organized an important conference for the end of June, to be attended by representatives from nearly every English-speaking University, the High Commissioners and Agents-General for the Dominions, delegates from the principal Chambers of Commerce, and others, has arranged a tour through the Dominion of Canada and the United States, of special interest to engineers and engineering students. The party will visit all the most important engineering works along the route, will be received and given information by commercial and industrial leaders in every sphere of activity and members of various governments. An important point is that the party is limited to ten people, to allow of specialization in particular subjects by individual members, and to enable it to be informative in the best sense. The itinerary will include Quebec, Montreal, Ottawa, Toronto, Cobalt, Sarnia (St. Clair tunnel), Chicago, St. Paul, Winnipeg, Regina, Calgary (railway constructon at nearest point), Banff and Laggan, Vancouver, San Francisco, Grand Canyon, Santa Fe, Laguna (Indian reservation), Pueblo, Denver, Golden, St. Louis, Pittsburg, Washington, Philadelphia (Cramp yards, etc.), New York and Boston, if desired. The party will be accompanied by a member of the Association who knows the countries visited, intimately. Further particulars can be obtained from the hon. secretary of the Association for the International Interchange of Students, at Caxton House, Westminster, S.W.

LARGE STEEL INGOTS.

Messes. Cammell, Laird, & Co., Ltd., have just turned out two very large steel ingots at their Grimesthorpe works, Sheffield. One of them weighs nearly 140 tons, and will form the base of an armor-bending or straightening press for a neighboring firm. It was cast from three furnaces, then reheated and placed under the 4,000-ton hydraulic press, in which its thickness was reduced from 4 ft. 6 in. to 3 ft. 6 in., and the top end, weighing about 40 tons, was cut off. After being again reheated, it was rolled down in the armor-plate mill to a thickness of 2 ft. 7 in. The second large ingot is an octagon of 137 tons, for a gun jacket.

R. H. Noble, who was employed by the Canadian Fairbanks-Morse Co. previous to his entering the organization of the Positive Clutch & Pulley Co., Toronto, has accepted a position with and now has charge of the transmission department of the Canadian Fairbanks-Morse Co., at Toronto.

FOUNDRY PRACTICE AND EQUIPMENT

Practical Articles for Canadian Foundrymen and Pattern Makers, and News of Foundrymen's and Allied Associations. Contributions Invited.

MODERN FOUNDRY PRACTICE*

By Hugh Munro, B.S.c., M.I., Mech. E.*

Molding.

NEARLY all castings are molded in sand molds. Of late a good many founders have experimented with permanent molds of cast iron for articles of which a large number is required. It is usually considered that castings made in iron molds are chilled and are very difficult or impossible to machine. This is not always the case. If the casting is allowed to cool in an iron mold it becomes very hard, or even white, but if it is withdrawn from the mold as soon as it will bear handling and is allowed to cool slowly, it does not become nearly so hard.

Permanent cores of cast iron are also used in a few foundries, and there is said to be no trouble in extracting them, provided they are drawn immediately after the metal has solidified. In using iron permanent molds, the molds must be warmed up to some extent before good castings can be produced from them, and the first half dozen castings are usually wasters. While on this subject of permanent molds, I may say that die castings made by injecting fluid metal into steel molds are quite common and can be made almost as exact as machine work. These castings are composed mostly of alloys of tin, lead, zinc and antimony; permanent molds for cast iron are still in their infancy.

Practically speaking, therefore, all castings are made in sand molds. The sand must have sufficient "bond" or cohesion to retain the shape of the pattern until the iron is poured, and it must also be sufficiently porous to allow all gases to pass freely away and leave a smooth skin on the resulting casting. Molds are made either in green sand, dry sand, or in loam.

Green Sand.

Green sand, so called because the mold, after drawing the pattern, is not dried in any way before the metal is run into it. This sand is mixed with a small proportion of coal dust, the object of the latter being to obtain a smooth skin on the casting and to prevent the sand sticking to it. It is most important to get the coal dust thoroughly incorporated with the sand, and for this purpose various mixers are used. The most successful are those of the centrifugal type.

Dry Sand.

Molds made in dry sand are dried in stoves or on the floor by special driers after the pattern is withdrawn from them. The mold is covered with a wash of blacking in order to give the casting a smooth skin and prevent the sand sticking to it. Coal dust is not mixed with this sand.

Loam.

Molds are built up of bricks and clay with iron plates to give the walls rigidity. The pattern may be complete and the mold built around it, or, if the casting is cylindrical in shape, part of the mold may be swept up by revolving boards or formers and the other sections made with skeleton patterns. Intricate and important castings of large size are usually made in loam. Complete patterns are necessary for both dry sand and green sand. In loam work, a few boards are frequently all that is necessary if the casting is of such a shape that it can be swept up. Ordinary molding sand should not contain more than 14 per cent. clay, 5 per cent. iron oxide, 1.5 per cent. lime, 1 per cent. organic matter. Silica should run from 75 to 85 per cent.

READER, WHAT DO YOU KNOW?

Among readers of Canadian Machinery there is a clearly defined sincerity of desire to know how each overcomes the daily tasks of the machine, pattern and blacksmith shops, the foundry and boiler shops. It is believed that your methods and devices, while good, may be improved, and thereby made more valuable if you publish them, so that other brains may work on them. We will provide the setting and pay you for the material. When your fellow tradesman puts the superstructure on your foundation, we pay him and pass the "kink" on to you, free. Get into the game.

Cores.

The proper construction of cores is of more importance than that of any other part of the mold. They are surrounded by metal, and they must be well vented in order that the gases generated in the sand may pass freely to the atmosphere. Cores are occasionally made in green sand, but more often in dry sand or loam. The sand should give off a minimum of gas, and it should be such that it may be easily cleaned out of the interior of the casting.

Of recent years many core compounds, or binders, as they are called, have been invented for mixing with sand to form cores. Linseed oil is one of the best core binders, but it is expensive. Resin, flour, and molasses are also good. Several very good binders which contain glucose compounds are now sold. These core compounds are mixed with ordinary sharp sand, and bind it together without any other ingredient, but a small amount of clay water is usually added. The great advantage of these core binders, such as linseed oil, is that they give off very little gas; they do not require core iron to stiffen them, and they bind the sand long enough until the iron solidifies. The heat burns up the binder, and the sand is easily cleaned out.

Preparation of Molds.

In a foundry, more skilled labor is employed in preparing molds than in any other operation, and it is here that most attempts have been made to cheapen production. Where there is a moderate amount of repetition work, a very effective way to reduce labor costs, and a way which requires very little capital expenditure, is the adoption of plate molding. Here the pattern for each half of a mold is fixed on a flat plate. The plates are made to receive the guide pins of the molding boxes, which are all interchangeable. All the bottom parts of the molds are laid down first, the cores inserted, and the top parts put on afterwards.

It is, however, by the adoption of machine molding that the greatest economies have been attained in most foundries. Molding machines may be worked by hand or power, and, generally speaking, they may be nearly all included in two leading types: (1) Machines which ram the mold and draw the pattern. (2) Machines which draw the pattern, the mold being rammed by hand.

Ramming Machines.

Ramming is done by squeezing the sand into the mold by hydraulic or pneumatic power, or by jolting. In the latter type of machine the molding box is filled with sand, the table of the machine is then raised and allowed to drop

---

* Continued from March issue of Canadian Machinery.

**Superintendent, Glenfield & Kennedy, Kilmarnock, Scotland.

smartly several times on an anvil. The sudden stop causes the sand to consolidate around the pattern. In order that this machine may be a success, the chief requisite is a massive anvil and a good foundation, but a form of jolt machine has recently been introduced in which no foundation is necessary.

Hydraulic machines usually ram the sand by one or two slow squeezes, while pneumatic machines ram it by several smart blows. Ramming molding machines are a success in flat, plain work, but where the mold is deep and the pattern intricate, some of the sand must be rammed by hand and the final squeeze given by the machine. The jolt ramming machine is said to ram the sand evenly all over deep and intricate patterns. As a matter of fact, the deep parts are rammed harder than the shallow places, and the sand at the bottom of the box is rammed harder than that at the top, owing to the weight of the extra sand above it. In a hydraulic or pneumatic machine, on the contrary, the top of the box is rammed harder than the bottom, and the shallow parts harder than the deep places.

Pattern Drawing Machines.

In very intricate work, the whole of the ramming may be done by hand, and the machine is then only used to withdraw the pattern from the mold. In drawing the pattern from the mold, it is of the greatest importance that the sand should be left absolutely intact and of the exact shape of the pattern. Except where the pattern is thin and has plenty of draft, precautions must be taken to prevent the sand adhering to the pattern or breaking away at the corners of the mold. In ordinary molding, the pattern is sprinkled over with some parting sand, which prevents the molding sand sticking to the pattern, and the pattern is rapped to loosen it before being withdrawn.

On molding machines, various devices are in use to enable the pattern to be easily and quickly withdrawn without injury to the mold. Cast iron patterns draw out of the sand more easily than brass or wooden ones, and both brass and iron patterns draw out more easily if they are kept warm, or if rubbed sometimes with paraffin oil. Pneumatic machines are furnished with a vibrator, which shakes the pattern very slightly and loosens it from the sand. Many pattern drawing machines are furnished with a stripper plate, which is a flat plate having a hole in it the exact counterpart of the outline of the pattern. The pattern is drawn through the plate, and the sand by this means is preserved intact. Thin patterns with plenty of taper or "draft," may be quite easily withdrawn without a vibrator or stripping plate, but deep patterns with intricate outline and little draft must either be vibrated or drawn through stripper plates.

At first sight it does not seem of much importance whether the pattern is drawn down from the mold, or the mold drawn down from the pattern. Both methods are in use, but it is more satisfactory to draw the pattern from the mold in such a way that the box may, during and after the operation, lie with the interior of the mold upwards. If a piece of sand adheres to the pattern it usually drops back into its place when this method is followed. The workman can at once examine the face of the mold and see that it is all in order, and that no parts are broken away. Where the mold is a very simple one the workman should not be allowed to patch up any defects in it. The sand should be knocked out, and a new mold rammed up.

Most molding machines ram the mold, turn it over and draw the pattern. Some of them simply draw the pattern down from the mold. Many others have a revolving table with the pattern for the bottom of the mold on one side and the pattern for the top on the other side of this table. The procedure is as follows: A box is clamped on the top side of the table, filled with sand, and rammed. The table is now turned upside-down, a box clamped on the other side, which is now the top side, and rammed. The first rammed box is then dropped from the pattern, withdrawn, and placed on the floor, when the table is again turned upside down, and the process goes on. On this type a complete mold may be made on one machine and each mold is finished before another is started, the top and bottom parts of the mold being made alternately. When the table does not revolve, the machine only carries one pattern. All the bottom parts of the mold are made first, and laid down; then the pattern is changed, and all the top parts are made and the molds finished off. Again two machines of this type may be used, one man making all the bottom parts, and another making all the top parts, while a third may be employed in placing cores in the molds and preparing them for casting.

In addition to the types already mentioned there are, in the United States, some machines in which the sand is consolidated by letting it fall into the mold from a height, or it is thrown into the mold with considerable force by other means. It is claimed that in this way the sand is equally rammed all through the mold.

Columns Cast on End.

Columns for building purposes are usually cast horizontally. Made in this manner the top side of the casting is weaker than the lower side, due to two causes: (a) The core tends to rise and make the top side of the casting thinner than the other; (b) All the dirt rises to the top or thin side.

Columns carrying heavy loads should be cast vertically. Rams for hydraulic cranes and accumulators are always cast on end. This insures clean metal of uniform section throughout the casting. The dirt rises into a "head," which is afterwards cut off. My firm make a specialty of cast iron columns cast on end, and have obtained the following tests from the metal used for this purpose:

65 tons per square inch in compression taken on cubes ½ inch square or ¼ square inch in area, and 13 tons per square inch tensile.

Defects.

The defects to which cast iron is subject, and which may render a casting useless, are numerous. The chief are as follows:

(1) Shrinkage defects.
(2) Blow holes—pin holes.
(3) Sand holes—slag holes.
(4) Hard spots.
(5) Cold shuts.
(6) Scabs.
(7) Irregular and rough surface.
(8) Out of section.

Shrinkage defects were dealt with under shrinkage.

Blow Holes—A blow hole or air hole is a hollow cavity in the metal usually having smooth walls of a bluish color, and as a rule it is quite empty. Blow holes occur mostly directly under the skin of the casting, but sometimes they are found throughout the whole section. The former are caused by the sand being too damp, too hard rammed, or badly vented; in either case the gases generated by the heat not finding a free escape through the sand are forced into the metal and form these cavities. Blow holes throughout the metal are probably caused by the metal having been cast too cold. It is doubtful if liquid cast iron occludes gas and gives it off during solidification. I am inclined to think it does not.

Chaplets (which are used to keep cores in position) are a fertile source of blow holes, especially if they are rusty or damp. They ought to be coated with pure tin, but often they are coated with an alloy of tin and lead or zinc, which is as bad as rust for causing blow holes.

The causes of blow holes are: Sand too wet; sand too hard rammed and badly vented; rusty or wet chaplets; air trapped in iron while pouring; gases generated in the iron while fluid, and possibly occluded gases.

Pin Holes—These are minute holes which appear on the surface, and often extend almost through the metal. They seem to proceed from a small piece of slag or oxide in the body of the metal from which gas is being generated by some chemical action. This gas forms a

small passage outwards for itself, and continues blowing through it until the iron has cooled, the result being a pin hole. It is said that iron high in sulphur is particularly subject to pin holes. I have tried the addition of manganese in order to prevent pin holes, but it had no appreciable effect.

Sand and Slag Holes—The cause of these is self-evident, either loose sand in the mold or slag entering the mold along with the iron. The mold should be thoroughly clean before being closed, and the iron should be well skimmed when pouring. When iron is being poured into a mold, some of it, of course, oxidizes. Oxide of iron has never, so far as I know, been found in cast iron. The oxide formed while pouring is probably reduced by the silicon present, and forms small particles of slag throughout the metal, and this slag may be seen under the microscope.

Hard Spots.—Hard masses of iron are sometimes met with when machining cast iron. These hard spots take the form of globules, which are sometimes covered with a skin of oxide; they are usually not united to, and may even be quite loose from the rest of the metal. They are sometimes found thoroughly united to the softer iron. These globules are said to consist of iron high in phosphorus, but more probably they consist of white iron which has been charged into the cupola along with other scrap and has not mixed with the rest of the metal during melting.

Cold Shuts.—When iron flows in a stream along a mold the advancing front gets covered with a thin film of oxide. If this stream meets another advancing towards it the oxide skin prevents the two streams uniting. The defect thus formed is called a "cold shut." It is often impossible to distinguish a cold shut in cast iron, but a water test soon shows it up. Globules of metal with a film all around them are often formed in castings, and, as they do not unite with the metal around them, the casting is thus weakened at that point. These globules are similar to those described under hard spots, but, except that they are soft, they do not differ from them, and are caused by a portion of iron becoming oxidised and subsequently not uniting with the rest of the metal.

Scabs. When part of the skin of a mold breaks away, which sometimes happens before the iron is poured into the mold or during that operation, the iron, of course, fills the place when the sand has fallen off, and forms on the casting a rough ugly lump called by molders a "scab." It is usually chipped off and does no harm to the casting, but the sand which has broken away must be somewhere in the mold, or, if a head is on the casting the sand will probably rise up there. Scabs are caused by bad venting, hard ramming, damp sand, or the mold crushing when being closed. When a flat plate is being made in green sand, the iron radiates heat to the top of the interior of the mold, and gas is generated in the layers of sand just behind the skin of the mold. If this gas, owing to defective venting, does not pass freely out of the sand, it blows back into the mold, taking some of the sand with it. To prevent this, all the risers in such molds are kept closed, so that the air inside is compressed. Gases generated in the sand cannot thus pass into the mold, but must flow outwards to the atmosphere while the compressed air inside exerts a slight pressure on the interior surface and prevents it collapsing.

Irregular Surface. When a casting has a lumpy, irregular surface, it is an indication that the mold has been rammed hard in some places and soft in others. A coarse, dirty skin on a casting is caused by the metal being poured very hot, or by a poor quality of facing sand or blacking.

When cores are placed in a mold they are kept in place by chaplets and by core prints. Sometimes the iron causes the core to float upwards, and then the metal on the top of the castings becomes too thin. This defect is very common in pipes and columns cast on their side.

Foundry Equipment.

The equipment of a modern foundry may assume a great variety of forms. If we consider a foundry doing general work of considerable weight, the chief consideration is quick and powerful cranes. Overhead electric travelers are used for dealing with heavier lifts and for traversing material through the shop, while wall cranes are used by squads of molders for handling boxes and molds. Cranes for foundry purposes should have facilities for specially slow handling of weights when important molds are being closed and cores placed in them.

In a foundry doing much light repetition work, the equipment consists of apparatus for dealing with sand and for getting iron promptly from the cupola to the molds. This latter is most important, as hot iron is an absolute necessity in light work. One of the most approved ways is an overhead runway, but ladles drawn along gangways throughout the foundry are equally common.

Drying stoves for molds and cores are usually fired by coke, and sometime? by producer gas. Coke is nearly always used. Gas fired stoves are easily controlled, and give a more uniform heat. The cost of coke and gas is about the same. Drying stoves nearly always open from the foundry direct, but this allows all the fumes and smoke from the stove to enter the shop. The stoves should be set back about 3 or 4 feet from main building, and both stove and foundry should each have independent doors. When the stove is being filled or emptied, both doors are open so that the smoke and fumes from the stove instead of coming into the shop ascend outside it.

The heating of a foundry is important in frosty weather. Molding sand for green sand molding contains a certain amount of water, and if this water freezes, the sand is useless for molding purposes for the time being.

The methods of cleaning castings are not greatly different now from what they were 20 years ago. The chief advance has been in the use of sand blast for cleaning out small intricate castings. These may be put into a revolving barrel and the sand directed to them there or they may be placed in a closed room and a man directs the sand on them through a nozzle. Pneumatic hammers have not been found of much service in dressing castings, as the amount to be chipped off varies to such a great extent. The old-fashioned revolving barrel holds its own against most modern methods.

Constituents of Cast Iron.

Iron for any particular class of castings is chosen most frequently by the appearance of the fracture. This method has produced excellent results in the past, and was a very good way when used by experienced men. Owing to the introduction of hot blast for blast furnaces, and harder driving, there is greater variation in the pig iron produced now than in the past, and fracture is not so reliable a guide to quality as it once was. It has been found that irrespective of the fracture, the chemical composition of the iron he uses is of great importance to the iron founder. The effect of certain of the constituents of cast iron is now fairly well known, and by properly proportioning these, more or less definite results may be obtained. Our knowledge of the influence of those constituents is to some extent deduced from investigation into their influence on iron in the form of steel. It does not necessarily follow that they affect cast iron in the same way, or to the same degree, as they do steel, although in some of the literature on cast iron this seems to be assumed by the writers. Moreover, the influence of any one constituent is usually modified by the relative proportion of other elements present, but what is stated here is accepted by the best authorities to be the result which may be expected from the different elements.

Effect on Cast Iron Due to Variation in Its Constituents.

Cast iron consists of the following elements in varying proportions:—Iron, carbon, silicon, sulphur, phosphorus, and manganese.

Carbon. Pure iron can only be melted with difficulty, but the presence of carbon (of which it is capable of holding in solution up to 4 per cent.) makes it comparatively easy to melt. At high temperatures it can hold more, as much as 4.5 per cent., but as it cools down, the excess separates out and collects on the top of the fluid metal in the form of "kish," which is often seen on pig iron, but not much of it is produced in the foundry. Ordinary foundry iron seldom contains more than 3.75 per cent. of carbon, and it exists in two forms, as combined carbon, and as graphitic carbon. Iron high in combined carbon melts at a lower temperature than iron with a high percentage of graphitic carbon. The former, however, is not so fluid as the latter, and it passes through a pasty stage in melting or solidifying. Combined carbon hardens iron and increases shrinkage; graphitic carbon has the opposite effect. With the latter, there is less tendency to blow holes and draw holes than with the former. An iron high in graphitic carbon is usually more satisfactory in the foundry so far as melting and casting is concerned. On the other hand, an iron low in graphitic carbon and high in combined carbon is much stronger.

Silicon. The direct effect of silicon on iron is obscure. It, however, acts indirectly on the iron through carbon in a very marked manner. Other things being equal, increase of silicon tends to force carbon from the combined form into the graphite form, thus softening the iron and decreasing shrinkage. It also weakens cast iron, and makes it more fluid. Silicon in molten iron readily unites with oxygen. When iron oxide gets into a mold along with the molten iron some of this oxide is reduced by the silicon and minute globules of slag are formed which are trapped in the solidifying metal, and quickly wear off the edge of cutting tools. If a soft easily machined metal is wanted, it is better to attain softness by graphitic carbon only than by graphitic carbon and high silicon. Silicon in the absence of carbon is said to harden iron.

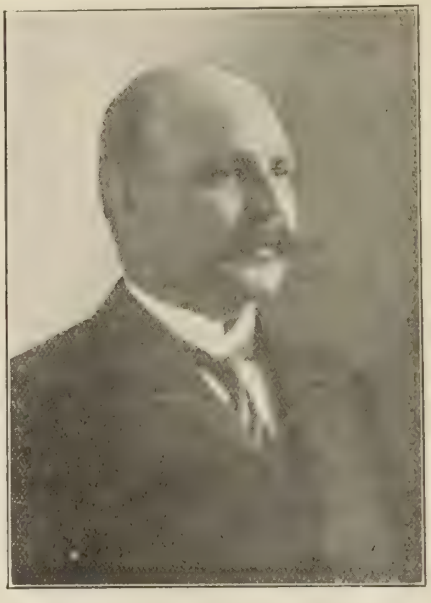
Sulphur. Sulphur hardens iron and is said to increase shrinkage. It is usually considered injurious to iron, but it improves heavy thick castings when present in quantities up to .25 per cent. When not exceeding this amount it increases the strength of thick castings but the proportion should be much less if the castings are thin. Sulphur has a tendency to prevent carbon assuming the graphitic form.

Phosphorus makes iron more fluid and apparently reduces shrinkage. Up to 1 per cent. or 1.3 per cent. it does not seem to affect the strength of cast iron greatly, although in very small proportions it has a bad effect on steel. A larger proportion of phosphorus than the above weakens cast iron very considerably. A phosphide of iron is formed which surrounds each individual crystal of iron and prevents them uniting as they otherwise would.

Manganese increases the capacity of iron to absorb carbon, and has a tendency to make the latter take the combined form. It hardens the iron and increases shrinkage, and when present in proportions of .8 to 1 per cent. it improves thick castings. Aluminum is sometimes used in small proportions in cast iron, but does not seem to be of much benefit to it. It appears to have the same effect as silicon but in a lesser degree. It tends to make carbon take the graphitic form.

THE LATE RICHARD R. MITCHELL.

Readers of Canadian Machinery will learn with regret that Mr. Richard Ramsay Mitchell, president of the Robert Mitchell Co., Ltd., Montreal, died on February 8, at his residence there. The deceased gentleman was born at Montreal in 1864 and received his education at the High School of that city. On



The late Richard Ramsay Mitchell.

leaving school he served an apprenticeship in the various shop and office departments of the Robt. Mitchell Co., and subsequently became a member of the firm. In the year 1896, the business was incorporated, and on the death of his father in the following year, Mr. Mitchell became president.

As a governor of the Montreal General and Western Hospitals and Board of Trade, Mr. Mitchell was well known and highly respected, while among those more directly interested in the foundry business, his vice-presidency of the American Brass Founders' Association indicated his personal worth and recognized executive ability. To those who were fortunate enough to know Mr. Mitchell in a social or business capacity, the news of his death comes with a double shock, for his generous disposition and hospitable manner will always be remembered.

GOOD MACHINES ATTRACT GOOD MEN.

A manufacturer of machinery, who has converted an old-time machine shop into one of the highest efficiency in methods and equipment, asserts that good machine tools bring good workmen. In his experience, which includes that of the evolution from the old-fashioned to the modern, he has found it very much easier to hire high-class workmen when they know they are to operate high-class machines. Probably one reason for this is that desirable men take pride in their work and want the best equipment with which to do it. A glance in the tool chest of a good machinist proves this statement, for he usually has an elaborate, well-cared-for kit of small tools and instruments. The man who is particular about his own tools must be attracted by modern machinery. Oftentimes he rates his chance of advancement by the amount of work he can produce, and the better the machine the greater the volume and the more satisfactory the product. Improved manufacturing facilities thus constitute an element which should not be disregarded in the general aim to secure efficiency.

A NEW MICROMETER.

A NEW micrometer that will be of interest to all machinists is being put on the market by the J. T. Slocomb Co., of Providence, R.I. It is an inside type for measuring one-half to two inches. There have been on the market for some time micrometers for making inside measurements, two inches and above, but a common method of making inside measurements, smaller than this, was by use of an inside caliper in conjunction with an outside micrometer. This at best was, of course, unsatisfactory. The J. T. Slocomb Co. are putting these tools up in sets containing inside micrometers only and also in sets containing their regular outside micrometers in addition.

MOULDING AN AIR CHAMBER COVER IN LOAM.

By J. H. Eastham.

THE air chamber cover, Fig. 1, was one of a set of condenser castings recently ordered. The contract price

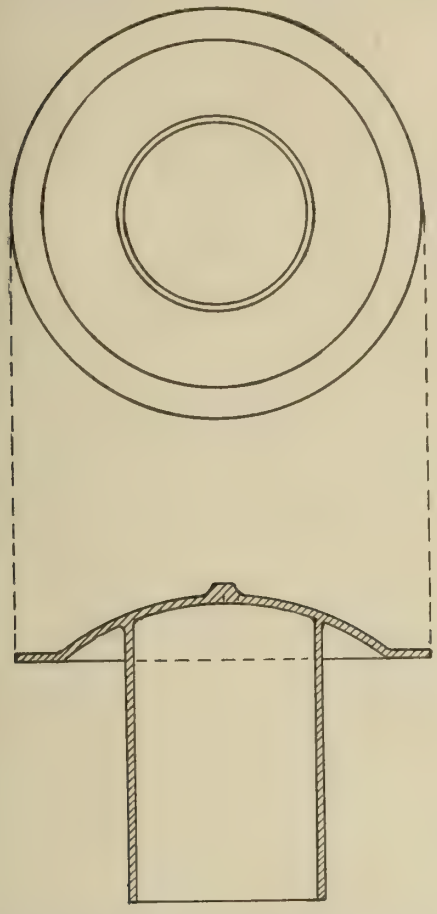


Fig. 1.—Molding air chamber cover in loam.

necessitated economy in patternmaking, therefore, this casting in common with others, was made in loam, the procedure being as follows.

Over a circular baseplate, several inches wider than the full radius of the casting, the sweep shown at A, Fig. 2. was set, brickwork being built up close to its under edge, and the outside or top face of the casting struck-up. When this, the plainest section of the mould was finished and run into the stove, the prodded plate B.B., Fig 3, was laid level, and the sweep, C.C. employed to strike-up the under side of the flange to match the section shown in Fig. 2. After being

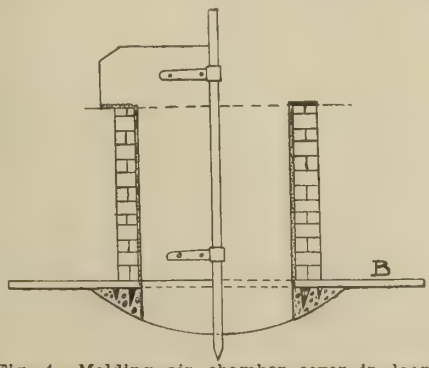

Fig. 4.—Molding air chamber cover in loam.

skin-dried, this plate was turned over, the full height of the casting built-up on

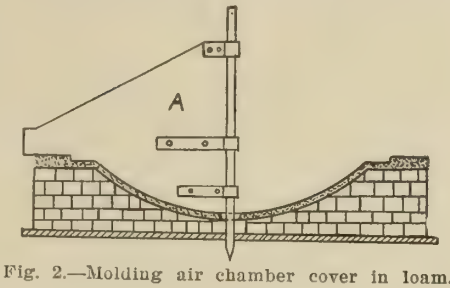

Fig. 2.—Molding air chamber cover in loam.

its reverse side, and swept-out by sweep D, Fig. 4; the outside or cheek portion of the mould being thereby completed.

The core was next built up on the cope plate E.E., Fig. 5, a binding plate F,

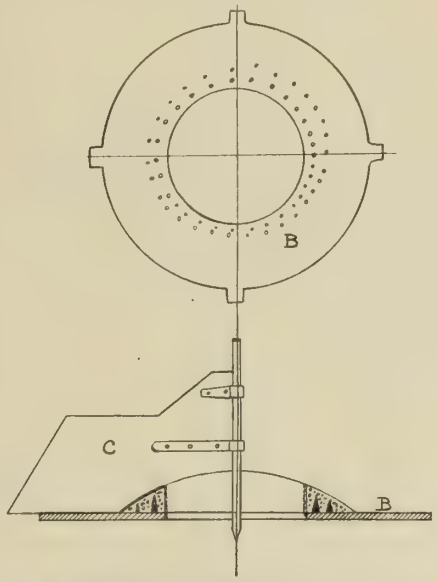

Fig. 3.—Molding air chamber cover in loam.

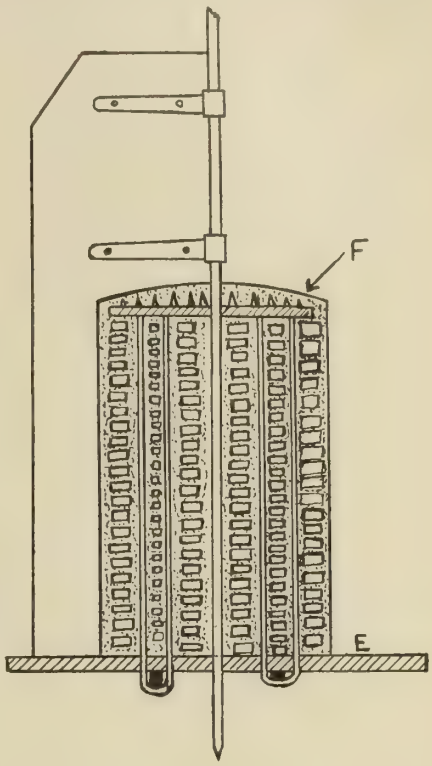
fitted with wrought iron loops being laid on the brick work and wedged to the cope to ensure rigidity. When closing the mould, the base plate was set in the floor to its full depth and rammed round tightly, the cheek being afterwards lowered to position. The cope plate, with core attached, was then tried on, the cheek fitted round with cribbing plates, and rammed-up in the ordinary way. On account of its unusual shape, weights were used to hold down the mould while pouring, the method of gating being shown in sketch of finished mould, Fig. 6.

FOUNDRY CONCERNS IN BIG MERGER.

J. A. MacKay & Co. have announced completion of the formation of the Canadian Foundries and Forgings, Limited, with the following capitalization:

	Authorized.	Issued.
Common stock	1,250,000	$960,000
Preferred, 7 p.c. ...	1,250,000	960,000
Bonds, 6 p.c.	500,000	67,000

This company consists of the James Smart Manufacturing Co., Ltd., Brockville, the Canadian Billings & Spencer, Ltd., and the Canada Forge, Ltd., both of Welland. The last two firms have been carrying on business for about five



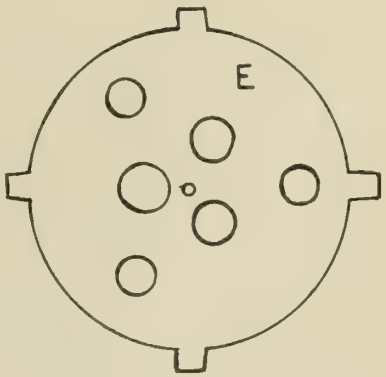


Fig. 5.—Molding air chamber cover in loam.

years, the Canadian Billings & Spencer being an off-shoot of the Billings & Spencer, of Hartford, Conn., one of the oldest concerns of its kind in the United States. Its output is of the nature of automobile parts and fine forgings, while that of the Canada Forge, Ltd., is of a somewhat heavier character, consisting largely of locomotive parts and heavy forgings of various kinds.

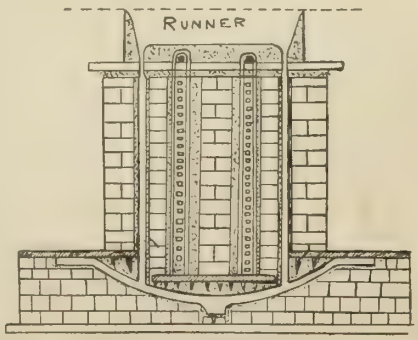

Fig. 6.—Molding air chamber cover in loam.

PANAMA CANAL LOCK TOWING SYSTEM.

WORK is advancing upon the locomotive tracks at both the Gatun and Pedro Miguel Locks. The tracks are to carry the electric locomotives which control the movement of vessels through the locks. It is necessary that each lock chamber be equipped with a towing track and return upon either side. This requires seven complete tracks at each of the locks—a towing and a return track upon each side wall, and a pair of towing tracks and a common return track upon the centre wall. All tracks extend the entire length of the lock walls and are provided with crossovers at both ends. The lines of the towing locomotives are fastened to the vessel in either the upper or lower forebay, and the locomotive then begins its travel; continuing at the rate of two miles an hour the entire length of the towing tracks. At the end of the run, the locomotive is transferred on the crossovers to the return track, upon which the return trip is made at the rate of five miles an hour.

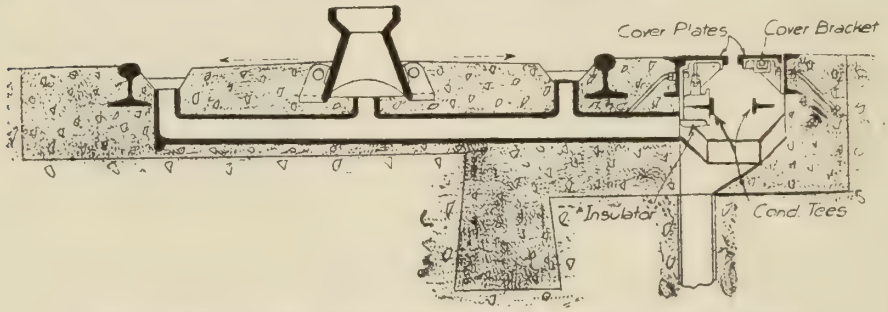

Fig. 2—Panama Canal—Large Scale Section of Towing Track, Showing Details of Rack, Conductor Slot and Drains.

In comparison with ordinary first-class railway construction, the locomotive trackage of the locks is unique. In point of durability, the system has no superior. The foundation is of concrete; the ties are of steel; the rails are heavy-weight—90 pounds to the yard; and, in addition, there is a rack for the towing track, a conductor slot housing a pair of electric rails for both the towing and the return track, and a complete drainage of surface, rack, rail gutters, and slot.

The installation is adapted to the ever varying features of the masonry construction. The towing track, which is subjected to the heavier duty, is in general supported upon the massive concrete adjacent to the edge of the lock chamber, a continuous, wide groove, 12 inches deep, having been left in the initial masonry as space for the erection of the track. The towing track is provided with heavy anchor bolts at each tie, spaced on three-foot centres and imbedded two and one-half feet in the concrete. Such anchoring is essential in order to provide against an up-pull of the thrust wheels on the locomotive acting against the rack, the thrust being possible in case of extraordinary side-pull of the towing lines, tending to overturn the locomotive. The return track is of somewhat lighter construction and, in general, is supported directly above the operating tunnels of the lock walls. The typical tie spacing upon the return track is 3 feet 9 inches, instead of three feet, as for the other. The tracks contain vertical curves between lock levels and horizontal curves at offsets; the former constructed on a 100-foot radius, and the latter on a 200-foot radius. Other special constructions are found at the cantilever decking over the indented recesses for miter gates, at the different crossovers, at the emergency dam inclines, at chain fender rooms, at intake and discharge valve rooms, and at a few manholes and cable shafts.

The accompanying illustration, Fig. 1, shows a typical cross-section of the towing and return track as installed. The towing track is situated 6 feet 9 inches to centre line from the edge of the lock chamber and rests upon the solid masonry of the gravity section of the lock wall. In this masonry, a channel twelve inches deep and a dove-tailed groove are left until the track and anchors have been set, when the concrete is carried up to final elevation, and the track and anchors thoroughly imbedded. The track material is furnished under contract; the ties, rack, and rails being drilled ready for connecting. In the field, the ties are spaced out, the rails spliced and bolted to the ties, as well as one side channel of the conductor slot. The rack is also bolted in position. The entire track is aligned and leveled, and the concrete cast, graded, and finished for proper drainage.

The surface of the concrete is sloped from the rack at the centre of tracks to rail gutters on either side, which gutters are sloped longitudinally to frequent outlets. At every outlet, a special cast-iron drain pipe, two inches in diameter, carries the water from each rail gutter and from underneath the rack to a sump situated at the bottom of the conductor slot on one side of the track. A four-inch drain pipe connects the conductor slot sump to a large drainage tunnel located underneath the duct space of the operating tunnel, fourteen feet below the coping. Other drains have a discharge at the conductor slot sump. This construction is varied to suit different requirements of centre wall return track, as well as other conditions. The finished appearance of the track is very trim, a relatively small portion of the rail being exposed to view and to the action of the elements in a tropical climate.

A rack, Fig. 2, for supplying the requisite traction is placed upon the centre-line of each towing track, as ordinary friction between wheels and rail is not sufficient for the maximum towing pull. The rack is of cast steel and of peculiar section, designed for the double purpose of engaging the driving cog of the locomotive and also a pair of horizontal thrust wheels; the function of which is to prevent overtipping of the locomotive in event of an excessive side-pull of the tow line. The pitch of the rack teeth is 3.13 inches, and each rack section is cast in lengths of six feet; being double tie-spacing. The sections are bolted together longitudinally and also bolted to each tie.

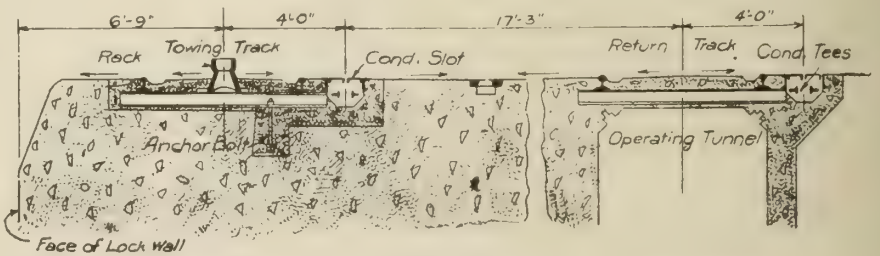

Fig. 1 Panama Canal—Section of Lock Side Wall, Showing General Features of Towing and Return Tracks.

The ties are rolled steel of modified I section, 5½ inches high with a top base of 8 inches and a lower base of 4½ inches. In railway work, it is common practice to install the larger base of the tie on the lower side to obtain a better bearing value. With a rail embedded in the concrete, the bearing value is of smaller importance, and the ties for the towing track are installed

with the larger base up in order to furnish more space for bolting the rack to the ties. A conductor slot is provided on the off-tow side of each track as a means of supplying electrical energy to the locomotive, which operates on a 3-phase circuit at twenty-five cycles and 220 volts. Two of the phases are carried through the conductor slot, whereas the third phase is connected to the two running rails and grounded. The two conductors in the conductor slot are of T-section and supported by clamp insulators from malleable iron brackets. For the towing tracks, the T-conductors are manufactured from copper ingots by the extrusion process, as considerable current-carrying capacity is necessary. For the return track, rolled steel T's are used as conductors. The conductor slot proper is 14 inches wide by 11 to 14 inches deep; the depth varying in order to slope toward the drainage sumps. The upper corners of the conductor slot are protected by five-inch channels imbedded and anchored into the concrete. Rolled steel checkered plates, in sections 30 feet long, cover the slot, resting upon frequently spaced brackets. A pair of contact plows, which bear against the flat side of each conductor rail and are attached to the locomotive, transmit the current from the conductors to the locomotive motors.

ROLLER AND BALL BEARINGS.

By Prof. John Goodman, M. Inst. C.E.

FOR the past 15 years the author has been investigating the behavior of both roller and ball bearings, in order to find the load and speed at which such bearings may be allowed to run. The object of this communication is to lay before the institution the results of a large number of tests of bearings, together with an attempt to reduce the mass of information obtained to a definite law. Two distinct types of testing machines were used: one for roller and ball bearings running on a cylindrical journal, and the other for thrust and collar bearings. These are described.

Roller Bearing References.

The common types of roller bearings are then referred to, and their relative advantages and disadvantages are discussed. Emphasis is laid on the serious troubles that arise from the end-thrust on the rollers The reason for the existence of end-thrust is dealt with and proposals are made for minimizing its ill effects. The machines used for measuring the friction of bearings and the end-thrust are described, and the results are tabulated. The tests show that the friction of roller bearings is much lower than that of ordinary bearings as commonly lubricated; the coefficient of friction is also more constant than with a plain bearing, being practically independent of speed and temperature. The starting effort of a roller bearing is little, if any, greater than the running resistance; a very important feature in machines which are constantly stopped and started. No satisfactory expression has been found for the safe load under which a roller bearing may be run. The various frictional losses that occur in a roller bearing have been analysed, and expressions are given for each.

Ball Bearing References.

Ball bearings are found to possess a great many advantages over rollerbearings; the friction is less, there is no end-thrust, and they occupy a much smaller length of shaft than either plain or roller bearings. Hertz's theory of the compression of perfectly elastic spheres and the stresses which occur in then when loaded is cited, and its application to the ball bearing problem is pointed out.

Very early in the author's experimental investigation it was found that the speed of rotation of the shaft and the balls makes a great difference to the working load that may be imposed on a ball bearing. It is shown that the centrifugal force acting on the balls does not materially increase the load upon them, hence the speed effect is not due to that cause. It is believed to have some relation to the well known effect of very rapid reversals of stress. The effect of running balls on flat and on grooved surfaces is dealt with, the experiments largely corroborating theoretical investigations.

The extreme importance of having all the balls in one race of exactly the same size, also of obtaining perfect truth and freedom from scratches in the ball races, is insisted upon. Expressions based on experimental data are given for the limiting working-load of ball bearings of both the thrust and radial types, and curves are plotted to show how the author's experiments agree with the tables found in makers' catalogues. The question of finding the load which will ultimately bring about failure in a ball bearing is one which presented some difficulty. Bearings which appear to be perfect to the naked eye after running for several months may ultimately fail if allowed to run for years. It is obviously out of the question to run test bearings for this length of time. Other methods, therefore, for detecting impending failure were tried, but without success, until the microscope was used for the examination of the balls. This method proved to be very valuable, and is believed to give entirely satisfactory results. The results of tests of ball bearings of different makes and designs are tabulated in an appendix. The design of bearings is also dealt with.

The author is of the opinion that modern ball bearings, as turned out by the best makers, are entirely satisfactory and reliable, and there is no reason to apprehend trouble with them. Reasonable care, of course, must be taken in mounting the bearings, and in ensuring that they are not allowed to run under higher loads than are given by the author's expressions. Ball bearings are more expensive to purchase than plain bearings fitted with ordinary lubrication, but the friction is about one-tenth as great, and the oil required is almost nil. When these qualities are taken into account, the ball bearing for almost every purpose is considered to be vastly superior to plain bearings. The paper, of which the foregoing is an abstract, together with illustrations of various types of bearing and curves giving the results obtained, was read recently before the Institution of Civil Engineers, London, Eng.

HEAP & PARTNERS (CANADA) LTD.

Heap & Partners (Canada) Ltd. have opened an office in Montreal to handle the Canadian business of Messrs. William Heap & Co., Liverpool, England, an old established firm who have been entensively engaged in the home and export trade for the last fifty years. Heap & Partners are Canadian agents for David Colville & Sons, Motherwell, Scotland; Samuel Osborn & Co., Sheffield, England, and Thomas Piggott & Co., Birmingham, England, manufacturers respectively of steel plates and bars, tool and implement steel, welded and riveted steel pipe. They will also carry galvanized and black sheets of every description and cater for such requirements as gas engines and producers, high speed steam engines, air compressors, turbine pumps, etc.

Mr. C. E. Gausden is managing director of the Canadian Company, and Mr. A. H. Atkins, A.M.I.M.E., A.M.I.E.E., one of the directors, having charge of the engineering department of the Liverpool office is spending a few months here to help along the introduction of the various specialties. The firm have also on their staff, Mr. E. S. Wilson, Sheffield, England, who, for several years was connected with the manufacture of high-speed tool steels.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

FOUNDRY AND MACHINE SHOP.

Victoria, B. C.—The Western Ontario Iron Company has been incorporated with a capital of $50,000. The directors are, M. B. Jackson, Victoria; J. W. Frost, Greenwood, B.C., A. S. Hood, Phoenix, B.C.

Saskatoon, Sask.—The following companies have been incorporated,—Northern Planing Mills with a capital of $50,000; The Fawcett Hardware Co., with a capital of $20,000; Saskatoon Construction and Engineering Co., with a capital of $20,000.

Edmonton, Alta.—The Van Syke Plow Co., has been incorporated with a capital of $10,000.

Toronto, Ont.—The National Iron Works, Ltd., are preparing plans and specifications which, when completed, will double the present capacity of their plant. Mr. Gordon F. Perry, manager of these works, is superintending the details of these plans.

Porcupine, Ont.—The building operations on the Pearl Lake Gold Mines shaft-house will soon be completed. It is the largest and the most substantial shaft house in the camp.

Port Mann, B.C.—It is understood that a plant for the manufacture of pig iron will be established here.

Chatham, Ont.—The Chicago Steel Brake Co., manufacturers of tinsmiths' brakes will move from their present location to a new plant which they purpose building in the spring.

Sarnia, Ont.—The H. Mueller Manufacturing Co., who received a bonus of $20,000 from the town, have not yet selected a site for their new industry. An option on the Standard Chain Works property is being obtained. They must invest $100,000 within the limits of the town in the industry of brass manufacture.

Vancouver, B.C.—It is understood on good authority that the Jenckes Machinery of Quebec will establish a branch factory here within the year and that they will be prepared to handle a very large business. All kinds of machinery will be manufactured and a large staff of men employed.

Hespeler, Ont.—The Hall-Zyrd Co. have removed here from Grimsby. The moulders have been busy for some time and the other departments are now under way.

Vancouver, B.C.—The Norton Griffiths Steel Construction Co., propose building repair yards here to look after their derricks, machinery, wagons, etc.

Neepawa, Man.—T. R. Deacon, manager of the Manitoba Bridge & Iron Works, was in Winnipeg recently, looking over the proposed site should the company decide to locate here.

New Westminster, B. C.—Messrs. Ackerman and Blakely have disposed of their patent rights on their draught excluders to the B. C. Brass Works on a royalty basis.

Port Colborne, Ont.—The Canadian Union Furnace Co. will erect a $500,000 plant here including a blast furnace and dock. Their product will be foundry and malleable iron, bessemer and basic pig, finished steel, etc. The concern will employ about 150 men, and is the Canadian plant of the Buffalo Union Furnace Co.

Stratford, Ont.—The ratepayers will vote on a by-law to guarantee the bonds of G. L. Griffiths of Melbourne, for $5,000, to open a factory for the manufacture of harness and hardware.

Port Colborne, Ont.—The ratepayers carried the two by-laws to the G. T. R. and the Canadian Union Furnace Co.

Niagara Falls, Ont.—The ratepayers will be asked to approve of an appropriation of $3,000 for a factory site.

Moose Jaw, Sask.—A prominent Canadian Sheet Steel manufacturing concern will build a large factory here in the near future.

Drummondville, Que.—The town has awarded the contract for its new power house. The Bishop Construction Co., Ltd., Montreal, who will construct the building, have sublet the following contracts,—(1) To the Wm. Hamilton Co., Peterborough for a 250 h.p. water wheel. (2) To the Allis-Chalmers-Bullock Co., Ltd. Rockfield, Que., for a 150 k.w. generator.

Saskatoon, Sask.—The Western Foundry and Machine Company are preparing to manufacture sewer pipes. They will erect a new warehouse and have purchased the right for Saskatchewan for the manufacture and sale of the Thomas glazed cement sewer pipe and have engaged an expert sewer pipe maker as foreman of the new department. The company are making the manhole covers used in connection with this city's sewer system. Mr. A. E. Small is general manager of this company.

Montreal, P. Q.—A report states that a new car construction company are considering the erection of plant in this city. No particulars or names are mentioned in the report.

Calgary, Alta.—It is reported that the Pioneer Tractor Company will erect a plant in this city. Dr. Wheelock, of Winona, Wisconsin, is interested in the matter.

MUNICIPAL.

Chatham, Ont.—On April 8th, the ratepayers will vote on a by-law granting certain concessions to the Canadian St. Mary's Machine Co.

Port Colborne, Ont.—The ratepayers contemplate granting certain concessions to the Canadian Furnace Company who propose to expend $1,000,000 on an iron and steel plant.

Vancouver, B.C.—The Dietrich Saw Works of Galt, Ont., will establish a branch in Vancouver.

Swift Current, Sask.—A six stall engine house and express building will be constructed by J. McDiarmid of Winnipeg.

Wetaskiwin, Alta.—The municipality contemplates expending $16,000 for waterworks and sewers.

Sandwich, Ont.—The council passed by-laws authorizing an issue of $4,952.82 for the Bedford St. sewer, and another for $9,385.25 for the Askin Ave. sewer.

North Toronto, Ont.—The council will submit a by-law to raise $60,000 for building a pumping station.

Moose Jaw, Sask.—The council contemplates expending $60,000 to install a high pressure water system.

St. Catharines, Ont.—The ratepayers will vote on a proposal to buy out the plant of the St. Catharines Gas Co. for $38,000.

Claresholm, Alta.—A by-law has been carried to spend $8,000 for waterworks purposes.

Port Stanley, Ont.—A by-law to expend $22,000 for waterworks purposes has been carried.

Kindersley, Sask.—The burgesses passed the by-law to provide $50,000 for waterworks purposes.

Richmond, Eburne, B.C.—The municipality proposes to expend $50,000 for a waterworks system.

Oak Bay, B.C.—The ratepayers will vote on by-law to raise $275,000 for sewer purposes and $75,000 for a waterworks system.

Moose Jaw, Sask.—The ratepayers will vote on a by-law to provide $170,000 for waterworks and sewer extensions.

Fort Frances, Ont.—The municipality propose expending $25,000 for sewage and waterworks.

Neepawa, Man.—The municipality contemplate expending $100,000 for extension of waterworks and sewage system.

Kindersley, Sask.—The municipality will expend $50,000 upon a waterworks installation.

Saskatoon, Sask.—The successful bidders for the supply of waterworks materials for Saskatoon, are as follows:—

For cast-iron pipe, the Canada Iron Corporation, $72,200.00; for valves and hydrants, Messrs. Drummond, McColl, $10,700.00; for corporation brass, the H. Mueller Mfg. Co., $3,000.00; for lead and iron pipe and service boxes, Messrs. Jas. Robertson Co., $8,500.00.

Niagara Falls, Ont.—The city is negotiating with the Provincial Government re the erection of a new power house and pumping station. The amount of power they intend to develop is about 4,000 h.p.

Sudbury, Ont.—The city calls for tenders for the following works:—(1) main sewer, 8,555 feet. 20 in., 18 in., and 15 in. (2) Sanitary sewers and force mains. (3) Sewer pipes and junctions.

London, Ont.—The council has applied to the legislature for permission to issue debentures, for additions to pumping plant apparatus and main extensions, to the extent of $61,000.

Hamilton, Ont.—The city will receive tenders for brass work for waterworks purposes, and other hardware, to be used in this connection.

Calgary, Alta.—The Commissioners recommend the submitting of by-law to provide $50,000 for sewer extensions.

Toronto Ont.—The municipal council intend to install the following water works material:—Two 36-inch mains under tracks, main pumping station to Front Street, $44,459; 42-inch main along Front Street to Bathurst Street, $55,048; 24-inch main along Niagara Street to Queen Street, $33,535; 36-inch main cross town line, Beverley Street to Sumach Street, $148,477; Two 15,000,000-gallon triple-expansion engines, including buildings and connections, $350,000. The existing debenture debt of the city (not including the Local Improvement Debt) is as follows:—General Debenture Debt, $26,415,642.30; Water works debt, $9,120,321.22; Debt for electric power distribution plant, $4,950,000=$14,070,321.22.

Guelph, Ont.—The Water Commissioners have awarded the following contracts for the supply of water works material: Galvanized iron pipe, the Bond Hardware Co.; brass goods, Miller, Limited, London; valves, Kerr Engine Co., Brantford; cast-iron pipe and specials, Gartshore-Thompson, Hamilton; valve boxes, Kerr Engine Co., Walkerville.

Toronto, Ont.—The Board of Control in dealing with the waterworks estimates did not strike out the item of $250,000 for two fifteen million gallon pumps connected to triple expansion engines and buildings, but decided that they should not come out of this year's taxes. A by-law to raise the amount will probably be submitted to the ratepayers in June.

Vancouver, B.C.—Tenders have been received for the trunk sewer and construction of laterals. The amounts varied between $126,055 and $89,071.

Hamilton, Ont.—The city is calling for tenders for a new waterworks intake pipe and for a steel conduit from the Beach Pumping station to the filtering basins.

Castor, Alta.—The ratepayers propose expending $40,000 for a waterworks system.

Stratford, Ont.—The ratepayers will vote on a by-law to guarantee the bonds of G. L. Griffiths of Melbourne for $5,000, to open a factory for the manufacture of harness and hardware.

Watrous, Sask.—The ratepayers passed the by-law providing for the waterworks system.

Port Stanley, Ont.—The ratepayers passed the by-law to provide $22,000 for a waterworks system.

Verdun, Que.—The town council carried the by-law to provide $229,000 for various improvements including waterworks and electric light extensions.

Digby, N. S.—The town will expend $15,000 on an electric lighting system.

Bassano, Alta.—Several by-laws regarding expenditures of approximately $200,000 are contemplated. One of the proposals is for waterworks and sewer extensions.

Scott, Sask.—The town will make extensive improvements on its waterworks system.

ELECTRICAL.

Wetaskiwin, Alta.—The municipality proposes expending $23,000 for electric lighting purposes.

Brampton, Ont.—Notice has been given for the introduction of a by-law to raise $12,000 by way of a temporary loan for Hydro-Electric purposes.

Medicine Hat, Alta.—A by-law will be introduced providing for the construction of a municipal street railway.

Moose Jaw, Sask.—The ratepayers will vote on a by-law to provide $225,000 for electric light extensions.

Dundas, Ont.—The Cataract Power Co., Hamilton, will erect a new sub-station here and remodel the lighting plant.

Toronto, Ont.—Fire destroyed the King Street car barns of the Toronto Railway Company, on March 25th last. The damage is estimated at $300,000.

Winnipeg, Man.—A report from this city states that the Winnipeg Electric Company has been sold and is now under the control of United States capital. The Manitoba Power Company are the purchasers and the report further mentions that the sub-companies are included in the sale. A complete appraisement of the value of the Winnipeg Electric Company is now being made by Messrs. Foster and Richardson of J. G. White & Co., of New York. A further staff is at work on plans of proposed extensions and developments, including that of the Big Bonnet Falls on Winnipeg River which will be carried out after re-organization at an estimated cost of $14,000,000. Rudolph E. F. Flinsch, treasurer of Messrs. White & Co., is in charge of the financial department of the work, representing New York bankers whose names will appear later. Joseph R. Choate, Jr., of New York, and W. R. Mulock, of Winnipeg, are attend-

ing to legal details. The price of the purchase is not made public, but is considered to be a large sum above $24,000,000.

Galt, Ont.—The Hydro-Electric Department will present plans fo ran ornamental street lighting system to the city council at an early date.

Verdun, Que.—The town council carried the by-law to provide $229,000 for various improvements including waterworks and electric light extensions.

Digby, N. S.—The town will expend $15,000 on an electric lighting system.

London, Ont.—The London & Lake Erie Transportation Company has signed a contract with the Hydro-Electric Commission for five hundred or more horse-power, at $28 per horse-power, $10,000 will be spent on new cars and other equipment.

Wilmer, B. C.—The Firlands Irrigation and Power Company, Limited, has been incorporated with a capital of $10,000, to operate and construct telephone and telegraph systems, tramways, etc., and to conserve water powers for the development of electricity, light or other powers, the head office is at Wilmer, B.C.

Coaticook, Que.—The town will install shortly a 250 k.v.a. generator. Tenders are invited.

Ottawa, Ont.—Plans have been filed here at the Carleton Co. Registry office in connection with the expropriation of the Chats Falls by the Hydro-Electric Power Commission of Ontario.

Sydney, C. B.—The Arena Rink Co., has been incorporated with a capital of $50,000. A modern rink will be erected at once. It will have its own up-to-date electric lighting plant and power house.

Davidson, Sask.—A new 62 h.p. gas-producer plant is about to be installed in the electric light plant to replace the old 36 h.p. plant.

Galt, Ont.—The Plumbers here are protesting against the action of the Hydro-Electric Dep. retailing incandescent lamps at an advance of 10 per cent. over cost.

St. Catharines.—The Crocker Wheeler Co., contemplate making a $60,000 addition to their plant here.

Port Arthur, Ont.—The municipality recently voted $75,800 for street railway improvements and $6,000 for an electric pump.

Niagara Falls, Ont.—Edson Pollard, representing an American Syndicate, offers to purchase the electric light plant for $6,000. A by-law will be submitted to the ratepayers shortly, re the proposition.

Innisfail, Alta.—The municipality propose to expend $15,000 for electric lighting purposes.

Verdun, B.C.—The council proposes to raise a loan of $229,000 of which $129,000 will be spent on the extension of the electric light plant, the increase of the water supply and the betterment of the fire-protection.

GENERAL MANUFACTURING.

Medicine Hat, Alta.—The Ogilvie Flour Mills will erect here a 9,000 barrel flour mill, oat meal mill, and cereal plant, the cost of which will be about $500,000. The city gives the company a free site and natural gas for ten years.

Toronto, Ont.—Prices Limited have been incorporated with a capital of $100,000, to manufacture and deal in bricks, tiles, pipes, artificial stone for building, paving and other purposes. The head office is at Toronto, and the provisional directors are David Henderson, W. H. McGuire and C. F. Rooney, all of Toronto.

Rosthern, Sask.—The Union Supply Co., Limited, will rebuild the flour mill destroyed by fire in December, cost about $20,000.

Stratford, Ont.—On April 19th next, the ratepayers will be asked to vote on a by-law to guarantee $8,000.00 worth of bonds for a knitting plant.

Toronto, Ont.—The premises of R. A. Sabbiston Company, horse blanket manufacturers, was damaged by fire to the extent of $100,000.

Toronto, Ont.—The Gendron Manufacturing Company and the A. B. McColl building were damaged to the extent of $10,000 to the former and $25,000 to the latter.

Toronto, Ont.—The plant of the Marshall Sanitary Mattress Company was damaged by fire to the extent of $8,000 recently.

Weyburn, Sask.—The elevator of the Western Elevator Company was destroyed by fire on March 19th last.

Wainwright, Alta.—The municipality proposes to grant a loan of $10,000 to assist a milling concern to locate here.

Moose Jaw, Sask.—The Robin Hood Flour Mills will be rebuilt with double their original capacity.

Moose Jaw, Sask.—A new 4,000 barrel flour mill will be erected here immediately. The mill will be in operation by the autumn.

Lindsay, Ont.—The Hood Knitting Company suffered a heavy loss by fire on March 28th.

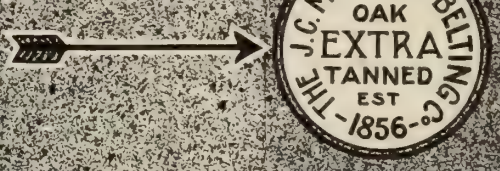
BEST LEATHER BELT MADE



TORONTO MONTREAL WINNIPEG
ST. JOHN, N.B. VANCOUVER

St. Catharines, Ont.—The Dominion Canners purpose erecting a factory in the Fonthill district and expect to have it completed for this season's work.

Fort Frances, Ont.—A big preserving plant is now in operation here, treating ties for railways. The present capacity is 1,500 ties per day, but will be increased three-fold during the coming season.

Saskatoon, Sask.—It is expected that a flour mill of 2,000 bbls. per day capacity will be erected here shortly.

Vancouver, B.C.—It is understood that the Dominion Bed Mfg. Co., of Kent, Wash., will shortly establish a factory here of 250 beds per day capacity.

Seaforth, Ont.—The Canada Furniture Co. have agreed to enlarge their factory and employ in the neighborhood of 60 additional hands if the town will provide a site.

Durham, Ont.—The Durham Furniture Co. have nearly completed the new addition to their factory and will employ 100 additional workmen in the near future.

St. John, N.B.—A piano factory will be established here this spring. Building operations will commence shortly.

Guelph, Ont.—C. J. Furber & Co., of Elmira, have decided to move their weather strip factory to Guelph and manufacture some additional lines.

Thorold, Ont.—The ratepayers granted a fixed assessment to a company of local capitalists for a large Pulp and Wood mill on lock 23 of the Welland Canal. The Company is capitalized at $1,000,000.

Courtright, Ont.—On Apr. 5th the ratepayers will vote on a by-law providing for a loan of $1,500 to the Western Construction Co.

Aurora, Ont.—The ratepayers passed the by-law to grant a bonus of $10,000 to the Collis Leather Co.

Smith's Falls, Ont.—The ratepayers will vote on a by-law to grant a loan of $25,000 to the Perth Shoe Co.

Ingersoll, Ont.—The ratepayers will vote on a by-law to grant a loan of $10,000 to the Ingersoll Motor Co.

Listowell, Ont.—The town contemplate offering some inducements to a biscuit factory to locate here.

Melville, Sask.—On Apr. 6 the ratepayers will vote on a by-law to grant $6,000 to start up a mill.

Lander, B.C.—The McLellan Lumber Co., are erecting a large lumber mill here and have applied to the Delta municipal for exemption from taxation and free water for a period.

Medicine Hat, Alta.—Work on the Preston Planing Mills will be started at once. When completed they will employ about seventy-five men.

Tide, N.B.—The Hardwood Planing Mills have been incorporated with a capital of $150,000.

Moose Jaw, Sask.—The Western Manufacturing Co., purpose erecting here the largest woodworking factory in the Prairie Provinces. They will employ upwards of 100 men all year.

Coquitlam, B. C.—The Canadian United Lumber Company have prepared plans for the erection of a new mill in this town. The Western Canada Power Company will supply the power to operate the machinery.

North Bay, Ont.—The planing mill of Jas. A. Cole & Co. was almost entirely destroyed by fire.

Orillia, Ont.—The planing mill of J. R. Eaton & Sons was almost totally destroyed by fire on Mar. 27th.

Vancouver, B.C.—The A. E. Olts Company, has been incorporated with a capital of $100,000, to carry on business as builders, dealers in timber, cement, and other supplies with head office at Vancouver, B.C.

Victoria, B. C.—Canadian Southern Lumber Company, Limited, has been incorporated, with a capital of $200,000, to carry on business as sawmill owners, lumber merchants and manufacturers of timber products, etc., with head office at Victoria, B.C.

Vancouver, B. C.—The English Bay Lumber Company, Limited, has been incorporated with a capital of $30,000, to carry on business as saw and shingle mill proprietors, pulp and paper manufacturers and general lumber and timber merchants, the head office is at Vancouver, B.C.

Nelson, B. C.—The mills of the Yale Columbia Lumber Company were destroyed by fire. The origin is supposed to be incendiary.

BUILDING NOTES.

Edmonton, Alta.—A new theatre and office building will be erected on the southwest corner of Second street and Jasper Ave. The building will be ten storeys and the bottom floor will be used for shops. It is understood that Geo. Brown & Co. of this city have secured a ninety-nine year lease on the property.

Fort William, Ont.—An addition will be built to elevator "D" which will increase its capacity from two and a quarter million

THE Manager of the Largest Works in Canada must at times feel the need of an inexpensive lathe for his private experimental work.

Much good thought and invention die out for want of easily and cheaply making experiments or models of an idea; a whole workshop of expensive tools usually being required, although the model needed may be small.

We have designed a tool for this work. A complete self-acting, sliding, boring and screw-cutting lathe, 4 in. centres, 2 ft. 4 in. bed, capable of doing all plain milling, keyway cutting, etc.

ITS COST IS $24.00 at Works in England

bushels to nearly three and seven-eighths million bushels. The cost will be about $400,000. Barnet and McQueen are the engineers and contractors. They will employ about 250 men. Work will be rushed to completion to enable the fall grain to be handled.

Vancouver, B.C.—Plans are being prepared for a theatre to cost $750,000 for the Vancouver Opera House.

Saskatoon, Sask.—The Y. M. C. A. have awarded the contract for the superstructure of their new building to Fred Lewis Co., Ltd., of Winnipeg at $69,300.

Edmonton, Alta.—A six storey building will be erected by the C. P. R. on the site of their present offices on Jasper Ave. The building will cost $300,000.

Toronto, Ont.—A fourteen storey building will be erected on lots 9-13 King St. W., by Dinnock Bros.

New Westminster, B.C.—The municipality is contemplating spending $100,000 to erect a three storey brick and terra cotta high school building, with concrete foundation. The building will be electric lighted, heated by fan system, slate roof, fir interior finish.

New Westminster, B. C.—Tenders have been called for to erect a theatre and office building costing $150,000, by the People's Trust Co. The building is to be eight stories, 64 feet x 32 feet, reinforced concrete and steel, electric lighted, seating capacity of theatre 1,450.

Woodstock, Ont.—The ratepayers will vote on a by-law April 15 to raise $75,000 for a new city hall.

Ottawa, Ont.—The government have purchased lots No. 21-31 Sparks St. for $257,000. A post office will be erected here, the equal of any in Canada.

St. John, N.B.—The C. P. R. will build a large elevator here.

Toronto, Ont.—Tenders are open for warehouse, cost $60,000, Wellington street west, for Copp, Clark Company, 64 Front street west. Architect, Wickson & Gregg, 59 Yonge street, Toronto. Four storeys, brick, concrete, foundation, steam heating, fire-doors, fire-brick, structural steel, cut stone lintels, tile coping, oak hardwood finish, reinforced concrete, steel rolling doors, boiler house, metal sash and lath, plate and art glass, ornamental iron, plunger and electric elevator, garage, Ohio cut stone. 177h.p. Multitubular boiler, 60-in. diameter and 16 feet long, with 83 3-in. tubes, oxide paint, fireproof paint, tar and gravel roofing.

Regina, Sask.—The Saskatchewan Motor Company have had plans prepared by Architect Van Egmond, Regina, for the erection of a garage, four storeys, 54 feet, corner Rose street and Victoria avenue. part of building fitted up for offices.

London, Ont.—The Hydro-Electric Commissioners will erect a storage building and patrol house in this city. The building will be erected on Horton Street, adjacent to the city's pumping station, and will be large enough to accommodate the water board's workshop. It is to be erected for the board of water commissioners.

Calgary, Alta.—The Calgary Herald intend to erect a ten-storey building on the corner of Seventh Avenue and First Street West. It will be of concrete and steel construction.

Edmonton, Alta.—Negotiations have been opened between the municipal authorities and Mr. J. S. Brody as to what location may be secured for the construction of a mattress factory.

Saskatoon, Sask.—A new warehouse is being rushed to completion here, by the agent of the Rambler Automobile Co.

Galt, Ont.—The Victoria Wheel Works will start operations at once on their new plant at River View Park. They expect to occupy them about July 1st and turn over their present premises to the C. P. R.

TRADE NOTES.

The Canadian Union Electric Co., capitalized at $45,000, and with head office at 9 St. Nicholas Street, Montreal, have been incorporated recently. They are connected with the Union Electric Co., of England, who are well known as the manufacturers of the Excello Flame Arc Lamp. The firm are specialists on lighting systems, including Electric Shadowless Lighting, sometimes called the Day Light System. They are also specialists on high tension switch gear, and manufacture motors and dynamos. The success which they have had in the Australian market has led them to open up a branch in Canada. They will carry a stock of arc lamps, switch gear, and motors of all sizes. Mr. Allan B. Wearing is managing director of the new company.

Williams & Wilson, 320 St. James Street, Montreal, have just published a catalogue of machinery and machinery supplies. It is a most complete and comprehensive collection, containing over 1,300 pages, and illustrated throughout with high quality engravings. The volume is bound in leather. The lines taken up will appeal to such establishments as steam railroads, electric railroads, marine shops, contractors, bridge builders, factories, machine shops, saw mills, paper and pulp mills, flour mills, textile mills, elevators and conveyors, electric light plants, waterworks, mines, etc., etc. The catalogue is available to prospective customers.

The Brown, Boggs Co., Ltd., of Hamilton, Ont., is contemplating an extensive enlargement of its plant, and for that purpose is negotiating for the purchase of six acres of land in the eastern part of the city, on the line of the G. T. R., and T. H. & B. Railways. The company is at present located at the corner of King William Street and Victoria Avenue, and if present plans go through will move from that section of the city as soon as the east end plant is erected. The capital of the concern will be increased to $500,000, and it is the intention to install an up-to-date plant and pay more attention to the manufacturing of tools and machinery.

The Robb Engineering Co., Amherst, N.S., are to instal a 150 H.P. Robb-Armstrong engine, together with boilers, smoke stacks, etc., for the Mountain Park Coal Co., who are located west of Edmonton, Alta.

Mr. E. Schofield has recently opened up an office in Montreal and will devote his attention to a number of Canadian agencies. Among the firms he will represent are the Canadian Tap & Die Co., The Galt Machine Screw Co., The London Foundry Co., The London Bolt & Hinge Works, the P. L. Robertson Mfg. Co., and others. For the past eight years Mr. Schofield has been acting in the capacity of Salesman for Alexander Gibb, manufacturers' agent, Montreal. Previous to this he was connected with B. J. Coghlin & Co., and Jas. W. Pyke & Co. Prior to coming to Canada from Manchester in 1900, Mr. Schofield served an apprenticeship to the engineering trade, and is thus competent to demonstrate, when necessary, the use of the various tools he is selling.

The Smart-Turner Machine Co., Hamilton, report the following orders recently received: The Point Anne Quarries, Toronto, centrifugal pump; the New Brunswick Pulp & Paper Co., Millerton, N.B., independent jet condenser; Grenville Board & Pulp Co., Thorold, centrifugal pump; Messrs. Cushing Bros., Saskatoon, Sask., duplex pump; the Jonquiere Pulp Co., Jonquiere, P.Q., duplex pot valve pump; the Big River Lumber Co., Big River, Sask., centrifugal pump; the Bird Woolen Mill Co., Ltd., Bracebridge, Ont., single acting triplex power pump; the Annette school, West Toronto, feed pump and receiver; the Dryden Timber & Power Co., Dryden, Ont., centrifugal pump; the Brown school and Manning Avenue school, Toronto, pumps and receivers; the Toronto Furniture Co., Toronto, simplex vacuum pump; the Steamer "Shuniah," duplex pot valve pump; the Intercolonial Railway, Stellarton, N.S., duplex pot valve pump.

The Hade, Davock & Beltaire Co. have recently been organized, with headquarters in Toronto, to devote special attention to the reorganization and systematizing of manufacturing concerns. The company is now engaged upon important work of this kind and have an organization well equipped in all branches of modern manufacturing and merchandising to take up the problems of scientific management, organization and sales.

The Joseph Dixon Crucible Company of Jersey City, has put on market a new chain graphite, especially intended for lubricating the chains of motor trucks and pleasure cars. This preparation is put up in sticks, cylindrical shape, 2 inches x 8 inches, encased in a neat cardboard carton and weighing about one pound each. It is made of the same material as the Dixon Bicycle Stick Graphite with which every bicycle owner is familiar. A bar may be carried on the car ready for use at any time. To apply, it is simply necessary to run the bar against the sprocket side of the chain. The "big stick" makes it easy to keep automobile driving chains in first-class condition. Unlike oils and greases, it will not collect dust and dirt.

Winnipeg—Messrs. Seimens Bros. Dynamo Works have been awarded the contract to supply the transformers and switchboards for the city. This firm will install the above previous to June 30th, 1912.

Ridgetown.—F. W. Farncomb, C. E., of London, Ont., acting for the Town of Ridgetown, has awarded the contract for the installation of the pumping equipment to the Canadian Fairbanks-Morse Co., of Toronto, for the sum of $7,500. The equipment will consist of one Fairbanks-Morse 60 h.p. natural gas engine, one Fairbanks-Morse 40 h.p. gasoline engine, two Smart-Turner double-acting triplex power pumps and three Goulds deep well pumps. The installation to be complete June 1st, 1912. The contract for the power house and pump well has been awarded to Geo. Poag, of Ridgetown, Ont.

Hamilton—The Gartshore Thomson Co. are about to erect an addition to their plant. This has become necessary owing to the large contract recently secured from the municipality for cast iron pipe.

Fort William—Tenders for 18-in. cast iron water mains will shortly be received by city engineer. Cost $45,000.

W. H. BANFIELD & SONS
TORONTO, ONT.

The Foss & Hill Machinery Co., Montreal, are moving May 1st, to their new show rooms at 344 St. James St.

The St. Lawrence Welding Co., Ltd., has been incorporated with a capital of $50,000. The office and shop are at 13 Roy Lane, Montreal. Edwin C. Richardson is secretary and general manager. The firm will do a contracting business in welding and cutting of all kinds.

The Dominion Oxygen Welding & Cutting Co., with head office and shops at 21 Queen St., Montreal, has just been formed. Company will undertake welding and cutting contracts of all kinds, using the oxy-acetylene process, and will specialize in marine work, boiler repairing and fixing broken machine parts. Several expert operators have been engaged. Mr. L. Vigoureux, late with R. J. Levy and the Blaugas Co., of Canada will be general manager, while Mr. A. M. Barry, late of the Foundation Co., Limited, is connected with the sales staff.

The George B. Meadows Co., Toronto, have presently on hand, in different stages of completion, contracts for metal lockers, steel shelving, stair and general ornamental iron-work equipment for the Toronto Furniture Co. new building; the Pathological Building, new General Hospital, Toronto; Toronto Hunt Club; Trinity Boys' School, Port Hope; New Parliament Building; Provincial Museum; Central Prison, Guelph; etc.

CATALOGUES.

The Simonds Canada Saw Co., Montreal, Que., have forwarded us a pamphlet giving a concise description of the saws, files and hack-saws which they manufacture. The great care in the selection and manufacture of the steel they use in their blades is emphasized. The cuts are excellent.

The Oeking Co., New York and Duesseldorf, Germany, have issued their catalogue No. AK 1912. It describes the firm's punching and shearing machinery, all of which are made with cast steel frames. Shears are made for plates, bars, angles and all structural shapes, and details of construction are fully illustrated and described in the catalogue. The firm's managers for the U. S., Canada and Cuba are the Weiner Machinery Co., 50 Church Street, New York.

Cling-Surface Co., Buffalo, N.Y., have issued Bulletin No. 321, a neat folder showing eleven noteworthy installations in Pennsylvania where Cling-Surface is profitably used on belts. Each illustration is accompanied by data concerning the belts shown.

SKF Single and Double Thrust Ball Bearings are described in a 16 page bulletin issued by the SKF Ball Bearing Co., 50 Church Street, New York. This bulletin is filled with sound arguments and good illustrations advocating their self-aligning double thrust bearing and their single thrust bearings with or without self-aligning seat. Self-alignment is featured throughout. A bulletin well worth sending for.

The Wheeler Condenser & Engineering Co., Cartaret, N. J., have just issued an attractive 16 page Catalog describing their various lines of condensing apparatus. In a preface entitled "Condenser Engineering" it is pointed out that each equipment is a problem in itself, and that it is necessary that there be a wide range of designs of Condensers, Cooling Towers, Pumps, etc., in order to provide combinations of these pieces of apparatus which will meet the requirements of load, vacuum, water, temperature, supply of water, etc., at the highest efficiency and least operating cost. The Wheeler Admiralty Surface Condenser, The Wheeler Volz Combined Condenser and Feed Water Heater and the Wheeler Admiralty Surface Condenser, Cylindrical Shell Type, are first described followed by a brief description of the Wheeler Dry Tube Surface Condenser and the Wheeler Rectangular Jet Condenser for high vacuum work. Subsequent pages are devoted to the Wheeler Barometric Jet Condensers, the Wheeler-Edwards air pump, Wheeler Rotative Dry Vacuum Air Pump and Wheeler Centrifugal Pumps. Two types of Cooling Towers, viz.: the Wheeler-Barnard for forced draft and the Wheeler-Balcks for natural draft are considered separately and are followed by a description of Wheeler Feed Water Heaters and Wheeler Atmospheric Exhaust Relief Valves. Copies of this Condensed Catalog may be obtained upon application to the Wheeler Condenser & Engineering Company, Cartaret, N.J.

The Detroit Lubricator Co. have put on the market an improved type of their standard sight feed lubricator, intended for use on steam shovels, dredges, logging engines, steam hammers and in other situations where there is great vibration. The improvement consists in a lug cast on the body near the bottom. This sits on, and is bolted to, a light bracket clamped to the main steam pipe, thus relieving the oil delivery pipe of all weight or strain and eliminating any possibility of damage to the lubricator from excessive vibration and jarring.

Mansfield & Sons, Ltd., Birkenhead, Eng., have forwarded their catalogue of oil gas apparatus for laboratories. This apparatus is intended for the use of scientists, whose laboratories are isolated from a supply of city gas, and this firm has supplied numbers of them to all parts of the world, one of the most recent installations being at the University of Alberta, Strathcona. The gas is made from mineral, animal or vegetable oil, and has a much higher heat value than coal gas. The plants are made suitable for bacteriological work and for ordinary chemical, physical and agricultural laboratories where a low constant temperature is required, and also for geological and metallurgical laboratories where temperatures as high as 1,500 deg. C are needed.

The Alberger Pump Co., New York, have issued a new catalogue of their centrifugal pumps and steam turbines. Their design and construction are fully dealt with and a section of the book is devoted to a review of the development and theory of the centrifugal pump.

The New Departure Mfg. Co., Bristol, Conn., have issued a well-got up catalogue and price list of all types of ball bearings manufactured by them. Numerous illustrations are given showing the various application of these bearings, and the methods employed in measuring and testing them before shipment, are also described in an interesting manner.

A. B. Jardine & Co., Hespeler, Ont., have favored us with a copy of their No. 14 catalogue and also folders descriptive of their forge blower and Canadian giant power hammer. The catalogue deals with the firm's well-know lines of machinists' taps, bolt threading machines, and tube expanders; also with tire benders and upsetters and other tools used by blacksmiths, carriage makers, etc. This firm has the most up-to-date equipment and shops and fully guarantee all their work.

The H. W. Johns-Manville Co. have sent us a copy of their Catalogue No. 112, descriptive of the J-M sectional conduit. This conduit is made from a mixture of stoneware clay, fireclay and spar and is intended to replace brick or concrete tunnels for underground piping systems. The conduit is made-up in short lengths, each of which is split longitudinally into halves, so that leaks in pipes are readily located after installation. The system is very fully described, and numerous plans of existing installations are given.

The Smooth-On Manufacturing Co., Jersey City, N.J., have forwarded a small pocket-edition 6¾x4½ in., of their latest catalogue. The general uses of this well-known iron cement are treated, and some particularly hard propositions which this utility has overcome, are illustrated.

We are in receipt of catalogue No. 13 from the **J. T. Slocomb Co.,** of Providence, R.I., illustrating their line of high-grade machinists' tools. The edition is of pocket size, being 5¼ x 7½ in., and the cuts are clear and illustrate the tools advantageously. Their line of micrometer calipers is particularly interesting. The book contains a price list also.

Hans Renold, Ltd., of Manchester, Eng., have forwarded us, through their Canadian agents, Jones & Glassco, a very attractive little booklet of pocket size. The outline of the book is the shape of one link of a driving chain, which is the sole product of the firm. A great many interesting facts about the firm and their product form the contents. The high grade and varied application of their chain is dwelt upon at some length. Their silent chain is also well illustrated, and its various uses defined.

Messrs. Herrgott Bros., Mildmay, Ont., have recently issued a new catalog illustrating their threshing machinery and cider mills. Their output has been largely increased due to the fact that they have built an addition to their foundry.

The 1912 edition of the catalogue of the **Heald Machine Co.,** Worcester, Mass., is of rather an elaborate nature. It reflects great credit upon those who were responsible for its appearance. Some excellent cuts of their plant greet the reader upon opening the book. These not only show the magnitude of the establishment and the attractiveness of the various departments of the factory, but the interest taken in the comfort of the employees. Very attractive illustrations of all their machines are shown, together with a complete description on the opposite page. The different forms and types of machines are too numerous to mention here. A useful chapter is one entitled "Points on Grinding" and no operator should fail to read this as a great deal of valuable information is available. A special portion of the book illustrates and describes a drill grinding machine. We are also in receipt of a booklet entitled, "Practical Hints on Internal Grinding" which contains a vast amount of excellent reading and advice. The beauty of it is that the work is very concise and easily understood. Another booklet received from the same firm

We have also a large stock of better rebuilts at slightly higher figures. Write for details. The Monarch Typewriter Co., Limited, 46 Adelaide St. West, Toronto, Canada.

contains a very interesting article on "Oversize standards for pistons and rings." A great many good ideas are expressed here. The writer advocates the gasoline engine industry to keep in stock oversize standard pistons and rings to supply to users of engines who have in some manner scored their cylinders so badly that regrinding becomes necessary. The information suggests a great many practices that can be employed profitably by both manufacturer and user. A pamphlet issued by this company entitled, "Cylinder Grinding" contains a wealth of information on this subject and no one interested in this work can afford being without it. Being of pocket size, 3½ inches x 6½ inches, it can be carried with one at all times which certainly enhances its already large field of usefulness.

The Goodyear Tire & Rubber Co., of Canada, Ltd., Toronto, have issued the first of a series of booklets to be got out covering all their lines of manufactured mechanical rubber goods. This first booklet deals with Goodyear Rubber Belting for driving, conveyor or elevator purposes, and contains useful hints on the selection and care of belts.

The Smart-Turner Machine Co., Hamilton, have recently received the following orders:—The Wm. Cane & Sons Co., Newmarket, Ont., Duplex Pot Valve Pump; The International Harvester Co., Chatham, Ont., Duplex Pump; The Oxford Foundry Machine Co., Oxford, N.S., Combined Air and Circulating Pump; Beardmore & Co., Acton, Ont., centrifugal pump; S. Caulfield & Sons, Parkdale, Ont., duplex pump; Toronto University, Toronto, centrifugal pump; Hamilton Bridge Works Co., Hamilton, standard duplex pump; J. H. Parent & Frere, Disraeli, Que., standard pump; International Harvester Co., Hamilton, centrifugal pump; The Port Dover Brick & Tile Co., Port Dover, Ont., duplex pump; The Canada Sugar & Refining Co., Montreal, Que., duplex pump.

BOOK REVIEWS.

"The Prevention of Railroad Accidents," by Geo. Bradshaw, New York. The Norman W. Henley Publishing Co. Price 50 cents. 173 pages, 6½ x 4½ inches, paper covers. The author of this little work was for ten years constantly engaged in the investigation and settlement of claims for personal injuries and deaths arising from railway accidents, and is consequently well qualified to speak of the causes and prevention of same. The book is addressed primarily to railway employes, the author pointing out how numerous are the accidents caused by non-observance, or by careless observance, of apparently unimportant rules. Numerous cuts are interspersed throughout the text, illustrating commonly found conditions that are prolific of disaster to life and limb. Pages 131 to 154 are devoted to safety devices in machine shops and form not the least interesting portion of the book, the whole of which we commend to the attention of railroad men.

FOUNDRY AND MACHINE SHOP.

The Peterborough Model Foundry & Mfg. Co., Peterborough, Ont., has been incorporated with a capital of 40,000. The incorporators are T. H. Ruble, J. Condon and W. H. Pethie.

The C. O. Clark Brass Co., Montreal, Que., will equip a new brass foundry.

STUART, DRINKWATER & HINGSTON, LTD.

Incorporation, with a capital of $50,000 has recently been granted to Stuart, Drinkwater & Hingston, Ltd., Montreal, The firm will represent in Canada, the Brush Electrical Engineering Co., London, Eng., dealing in their complete line of electrical machinery, electric rolling stock, and electric supplies. In addition, they will represent Messrs. A. W. Penrose & Co., also of London, Eng., manufacturers of the Penrose electric elevators. They will take over the Canada Ford Co., Ltd., of which Mr. Stuart is president; Mr. Drinkwater, vice-president, and Mr. Hingston, secretary-treasurer—these three gentlemen constituting the sole shareholders of the companies.

Steel Foundry For Sale

The undersigned are prepared to receive tenders for the property and plant belonging to the Parker Foundry Co., Ltd., in Liquidation. The Factory is situated at No. 27 Tansley Street, Montreal (off Delorimier Avenue), and the property has an area of about 16,800 square feet. The Factory, which is well lighted, covers almost the entire area of the property, and the plant and equipment has been installed within the past few years, and is in good condition. The Company had obtained a good and growing market for its castings, and it is believed that much of the trade could be retained by an early purchaser.

All tenders must be accompanied by a certified cheque for five per cent. of the amount of the tender, which will be retained on account of the purchase price if the tender is accepted.

Terms of sale are cash.

The Book Debts of the Company in Liquidation are expressly reserved from the assets offered for sale.

The Company's plant comprises both steel and grey iron equipment and appliances.

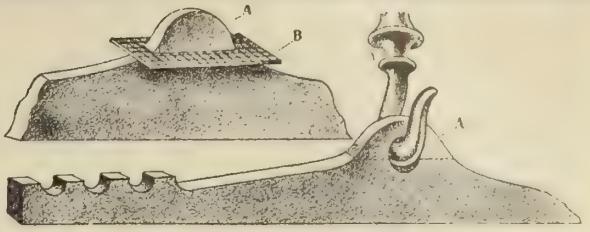
The property and plant can be seen at any time, and a detailed inventory of the plant can be examined at the Liquidators' Office.

Offerers will be held to have satisfied themselves as to the condition of the property, and the business, plant and property will be sold without warranty of any kind.

The acceptance of any tender is subject to the approval of the Court, and the highest or any offer will not necessarily be accepted.

A. C. STEAD,
JAMES HUTCHISON,
Joint Liquidators.

80 St. Francois Xavier Street,
Montreal,
April 1st, 1912.



METHOD OF WELDING STEEL CASTINGS

In one instance $1.00 worth of
LAFFITTE WELDING PLATES
saved $240.00 worth of steel castings.

You can effect the same saving in innumerable ways. There are thousands of jobs seemingly unimportant, that, if welded or repaired by welding, would positively save you hundreds of dollars. The LAFFITTE method gives perfect results in one-third the time, fuel and labor. There is no change in method and no special equipment necessary.

LAFFITTE Welding Plates homogeneously weld anything of iron or steel—from Norway iron to high speed tool steel.

Not an Enterprise for the "Quitter"

¶ "If there is one enterprise on earth," says John Wanamaker, "that a 'quitter' should leave severely alone, it is advertising. To make a success of advertising one must be prepared to stick like a barnacle on a boat's bottom.

¶ "He must know before he begins it that he must spend money—lots of it.

¶ "Somebody must tell him that he cannot hope to reap results commensurate with his expenditure early in the game.

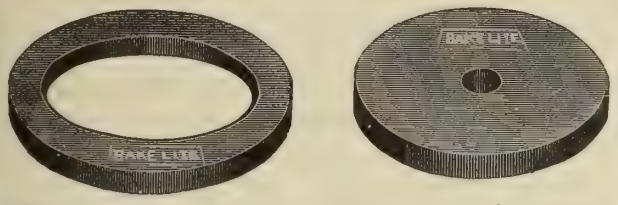
¶ "Advertising does not jerk; it pulls. It begins very gently at first, but the pull is steady. It increases day by day and year by year, until it exerts an irresistible power."

The advertiser would like to know where you saw his advertisement—tell him.

These are the telling points about

Bakelite

Valve Discs



They will not leak under high temperature, excessive pressure or when used in acids or other special liquids. Neither cold water, dry or superheated steam has the least effect upon them. BAKELITE Discs are a gas-tight fit.

BAKELITE is a successful substitute for expensive metal. Its structure is fibrous, giving strength and hardness. It can be reground and refaced, always retaining a uniform surface. It cannot be injured except by accident or friction.

Remember Bakelite PUMP VALVES do not warp with changes of temperature.

Order your valves fitted with Bakelite Valve Discs and stop that perpetual annoyance and expense caused by leaking valves. Depend upon it, Bakelite Valve Discs will not leak.

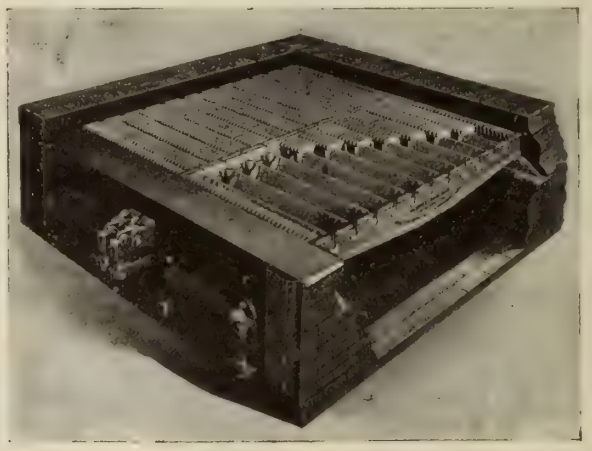
Change the Air Spaces

It is easy and inexpensive to alter the air space if coal is changed, for the removable tops can be furnished with any desired air openings. It's just as easy to replace a few burned out tops.

The points break up the fire without slicing, for they penetrate twice as far as other shaking grates with the same motion of the lever.

MACDONALD SHAKING GRATE



Points cannot become burned off, for the lever can be inserted or withdrawn only when the grates are level.

MORE AIR

FOR THE MONEY

The class "NE-1" compressor delivers more air for the money invested and the power consumed, month after month, than any small compressor heretofore offered. It should, however, it's manufactured to be a leader. It embodies all the modern ideas in air compression.

The "NE-1" is obviously an aristocrat. When you consider its construction: the large, amply oiled bearings, the perfectly balanced rotating and reciprocating parts; the large, free air ports; the high grade workmanship and many other features which it embodies, and which are detailed in our Pamphlet K-92, you will agree with us that it is a superior little machine.

Riveting By Electricity

NO PUNCHING
REAMING
RIVETING

Reduce three operations to one by Electric Welding. Secure greater efficiency and save three-quarters of your present labor charges. **Why** follow old methods, when new ones will make you larger profits? **We** are not limited to one-eighth of an inch in thickness of metal. We can weld heavy material as well as light, and our machines adapted for heavy work will also take care of light work. **Send** us sample or write for particulars.

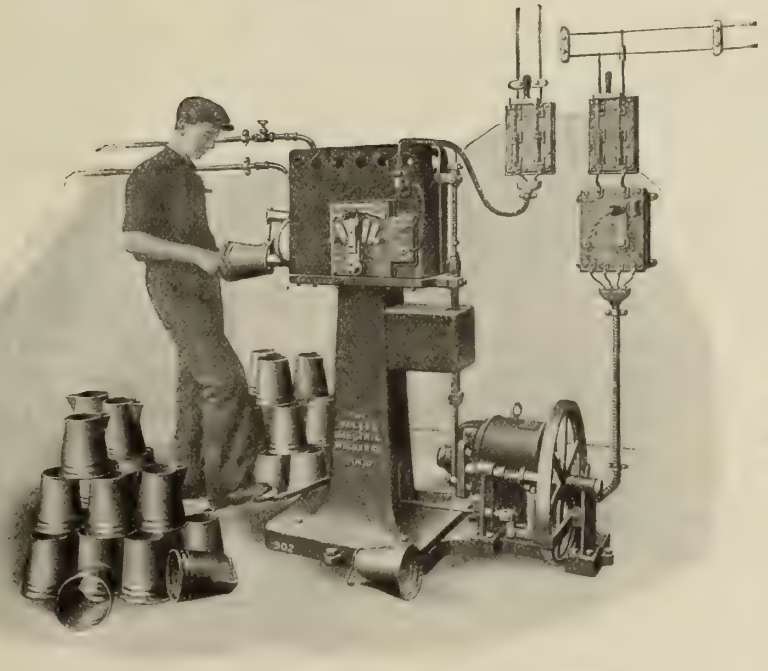
Electric Travelling Cranes
(Direct or Alternating Current)

Steam and Electric Derricks
(Stationary or Travelling)

Up-to-date design. Built for fast, continuous service.
ACCESSIBILITY—DURABILITY.

Dominion Bridge Company, Limited
MONTREAL

50,000 to 65,000 Welds Per Day Can Be Made on This Machine



This is our New No. 24 Automatic Power Driven Spot Welder.

NO HOLES TO PUNCH.
NO RIVETS USED.

Complete with direct current variable speed motor, by means of which this machine can be speeded up from 60 to 120 welds per minute.

Equipped with automatic switch—water cooled dies—self contained regulator on the side of the machine, adjustable to varying thicknesses of stock from 18 to 30 gauge.

Works automatically. Boy presses down on the treadle, engages a clutch and starts the machine. Can make one weld or a number, just as he desires. The automatic switch opens and closes the circuit, and the instant he takes his foot off the treadle, the machine stops.

Give us your address and let us tell you more about this new No. 24 and our 60 other different types of welders. And we will send you **FREE** our new No. 11 Bulletin, too.

NO LEASE. NO LICENSE. NO ROYALTY.

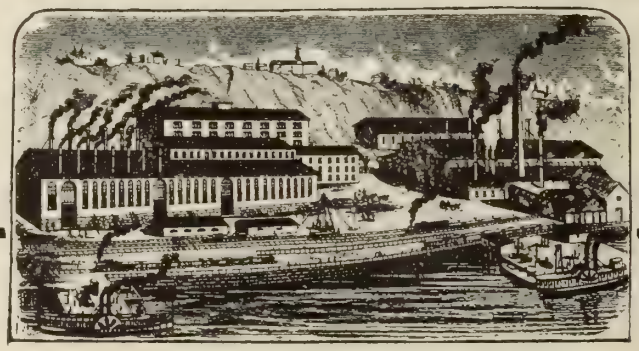
MARINE ENGINES and PUMPS. SHOE MACHINERY A Specialty



BRASS and IRON CASTINGS. BOILERS and REPAIRS.

That we have exceptional facilities at our disposal for the manufacture of all kinds of Machinery —in addition to our business as Brass and Iron Founders, General Contractors and Shoe Machinery Engineers—has been amply proved this year. In the short space of five months, we built and installed all the Engines and Boilers of the new sister steamers "Levis" and "Lauzon," whose trial trips were a complete success. We make a specialty of all kinds of Marine Engine Work, and shall be glad to quote for first-rate products only.

SHOE MACHINERY. Manufacturers of "Non-Royalty" Machines, Metallic and Goodyear, "Fortuna" Skivers, and "Climax" Presses, Sand-papering, Lasting and Loose Studding Machines.

What are Your Twisted off Tangs costing You ?

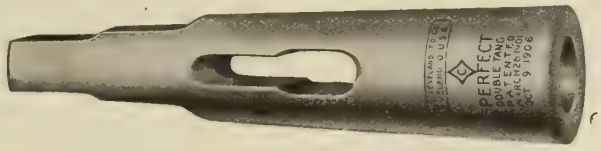
The broken tang was only .312 inches in thickness.

The new tang is .500 inches in thickness.

Good for the Scrap heap.

Have you ever considered what it is costing your shop to throw away taper shank tools with tangs twisted or broken off? It is a great waste of good material that *should be saved* and *can* be.

Patented Mar. 25, '01



Patented Oct. 9, '06

"PERFECT Double Tang" SOCKETS

not only prevent the tangs on your new drills twisting off, but also make your tools with broken tangs stronger and better than they were when new.

Simply grind a second and stronger tang on the shank below the original one. It is 25% to 60% thicker than the original tang according to the size of the shank. The Double-Tang Sockets do the rest.

Fit any Drill Press or Lathe Spindle

Made in all Styles and Sizes
Ordinary Drift removes Drills

Send for Folder 19-C.

Ready for the Drill Press

Interesting Information For Drill Users

Long after other steels have found their place in the scrap pile, "Sisco Acorn" steel will be doing profitable work.

The Scrap Pile tells the story of quality. There you have a concrete proof of the comparative qualities of steel. The less the better.

"Sisco Acorn" is not at home in the scrap pile. It believes in wearing out, not rusting out.

"Sisco Acorn" is a long lasting Drill Steel.

No Drill Steel User in the United States has stopped buying "Sisco Acorn" after having tried it.

Why don't you try it under our guarantee?

If You want Your Drills to do more work See this seal in your dreams.

PUT A BETTER EDGE ON YOUR TOOLS

BY USING

BLOUNT'S

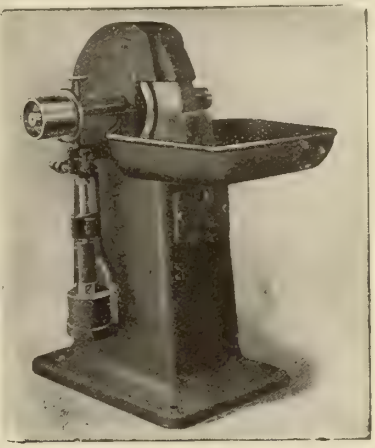
Wet Tool Grinder

This grinder can be run continuously if desired, at practically no cost.

It is fitted with self-oiling bearings, so that there is no wear of parts.

The propeller of the pumps which furnishes a constant supply of water, is loosely fitted and does not touch the case at the nearest point. A sleeve cap prevents leakage without the use of packing.

This is a machine that is not expensive—you cannot afford to be without it.



Write for catalog at once.

J. G. Blount Company

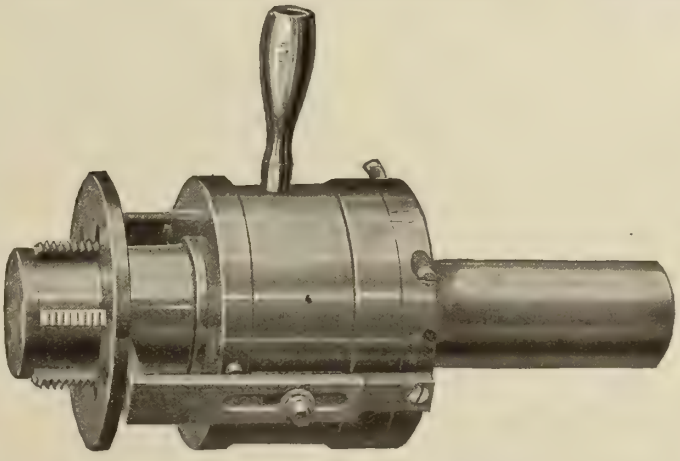
EVERETT, MASS.

Are you trying to do your tapping with solid taps? Why continue to do so?

GEOMETRIC COLLAPSING TAPS

Fitted to your Drill Press or Turret Lathe will do the work in **HALF THE TIME**—and do it **BETTER**. Therefore, the **GEOMETRIC COLLAPSING TAP IS YOUR TOOL.**

While cutting they are as rigid as solid taps, but at the end of the cut they collapse their chasers automatically and are withdrawn without backing out. This gives a perfect thread always.



Will tap either straight or standard pipe thread sizes.

Will tap diameters slightly larger or smaller than the exact size for which the tap is made.

Will permit of advancing the chasers to allow for wear, so that one set of chasers will last much longer than any solid tap, and can be renewed at very small cost, while the tap remains as good as new.

Tell us what your tapping requirements are, and we will quote you a Collapsing Tap that will take care of them.

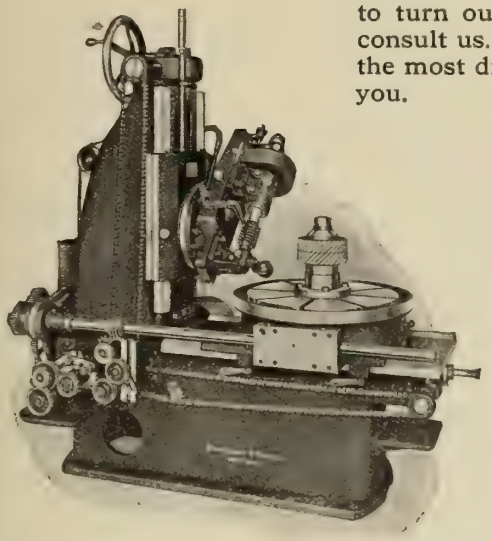
You Can Cut Spiral Gears As Easily As Spur Gears

On the S & S Gear Hobbing Machine



If you have trouble with your present gear cutting department or are unable to turn out accurate and noiseless running gears, you should immediately consult us. A substitution of spiral gears for spur gears has solved some of the most difficult problems. What we have done for others we can do for you.

S & S Gear Hobbing Machines are equipped with an ingenious device for cutting spiral gears which is strongly protected by patents and cannot be imitated by anyone, nor can the same results be produced by any other method.

S & S Machines are, by virtue of their patented features, the only practical gear hobbers for cutting spiral gears of any lead to absolute accuracy within the limits of .00001 independent of the feed gears and without necessity of tedious figuring.

Right and left hand spirals cut with same hob. One hob will cut any size gear of one pitch.

Write for particulars.

Schuchardt & Schutte

307 Coristine Bldg. - Montreal, Que.

The Economy of Milling Attachments

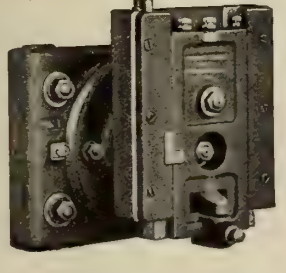
In a small shop—

They enable an endless variety of work to be done on one machine, saving the cost of additional machines and floor.

In a large shop—

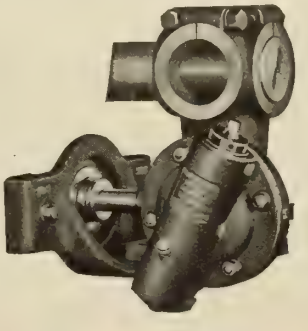
They are valuable for performing several operations on a piece at one setting. Also where an operation is to be done that would otherwise require a machine located at a distant part of the shop, or one in which a job is already set up, an attachment can often be used to advantage.

The B. & S. Line of Milling Machine Attachments



is very complete, comprising attachments for many varieties of work. Some of them are:

High Speed Milling Attachments.
Vertical Spindle Milling Attachments.
Universal Milling Attachments.
Slotting Attachments.
Rack Cutting Attachments.
Cam Cutting Attachment.
Circular Milling Attachments.
Index Centres.
Tilting Table for Taper Milling.



We have special circulars illustrating and describing these attachments. If interested, send for copies of any one or all. They are free.

NEW
Outside Spring Calipers with Patent Rule Attachment

It is so made that zero will always come in line with one caliper point—there is only one easy reading to make.

When folded back out of use the rule is held by a snap-catch.

5-inch Fay No. 75 outside calipers with quick adjusting spring-nut—4-inch rule graduated in 32nds and 64th. Send for descriptive folder No. 139. Price $2.25.

This is one of the many fine tools we make. Get the Starrett 274-page catalogue. There is much information in it, which will be useful to you.

Send for Catalog 193.

SMOOTH-ON

IRON CEMENTS

Positively stop all leaks of steam, water, fire or oil. They are easy to apply, harden quickly and when hard, expand and contract with the iron.

Every engineer should have a copy of our instruction book.

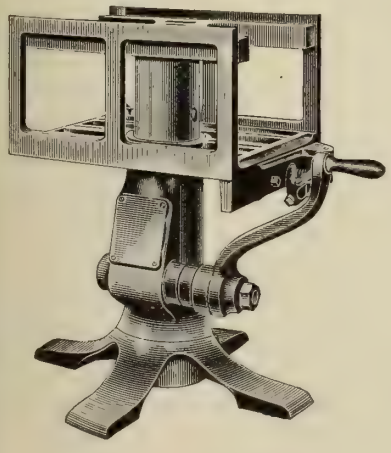
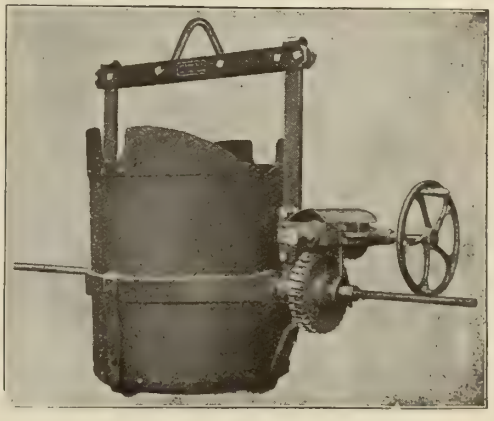
MONTREAL, CANADA

PROMPT SHIPMENTS





This is something that every foundryman wants when he orders his goods.
We are prepared to give you service, quality, and lowest prices on anything from a DUST BAG to a CUPOLA.
If you are not using EUREKA BLACKING you ought to. It's the BEST on the MARKET.
EUREKA CORE COMPOUND (a pitch core compound) of 100% purity, mixes much the same as flour and as readily taken from the castings. Will not blow and is cheaper than flour.
No. 48 PLUMBAGO, a high graphitic carbon lead, will do the best kind of work, if you are looking for that kind. Write for latest catalog of Polishers' and Platers' Supplies.

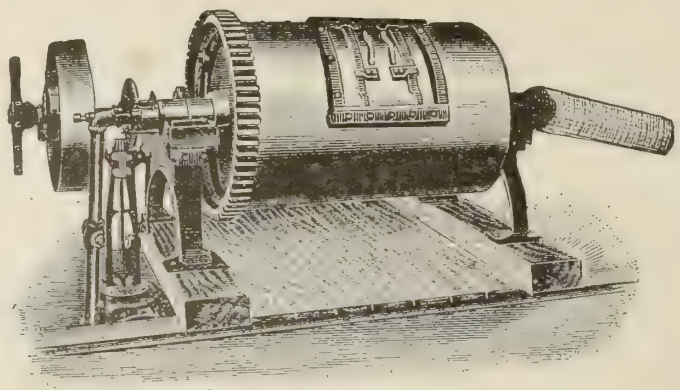
A GOLD MINE

SAVE YOUR IRON



SLY'S PATENT IRON CINDER MILL
Patented, No. 514097. Patented, No. 841728.

may be at your disposal on your very premises. Look out of your side window or back door and see if you have not an accumulation of cupola dump, and other foundry refuse, which is a total loss to you in its present state. Why not add to your profits and install one of the Sly Patent Cinder Mills to reclaim this iron and be astonished at your former loss and pocket the rich returns from your newly-discovered mine.

Sly's Patent Iron Cinder Mill will save 95% of the iron contained in your cupola dump and gangway scrapings and 75% of the coke. Iron is valuable, then why throw it in the dump? Iron recovered by this Mill is better than machinery scrap. Study economy in a foundry and your profits will increase accordingly. Mill will pay for itself three or four times every year, and we have records of Mill paying for itself twelve times a year. Let us know amount of your daily melt and we will quote. *Write for Cinder Mill Catalogue F.*

We also manufacture Cleaning Mills, Dust Arresters, Sand Blast and Foundry Equipment.

THE W. W. SLY MFG. CO., CLEVELAND, O.

The advertiser would like to know where you saw his advertisement—tell him.

"I Want What I Want When I Want It— It's All That Makes Life Worth the While."

TRULY SAID—isn't it? Even if it is a verse of a popular song. The subject applies directly to business. It's getting the goods of the right kind at the right time, that means money to you. If you are delayed in getting what you want, you can't profitably plan your production. Possibly you can't even deliver your goods when contract time calls for them. Either situation means a loss.

There is one firm that can give the kind of service that your foundry demands.

The products are the very best offered and you are absolutely sure of prompt and courteous attention.

We carry ready for shipment from our warehouse at **Windsor, Ontario:**

PLUMBAGO-LEAD-GRAPHITE

The EAST INDIA LEAD—direct from India, has an envious reputation—**none is so pure.** A well-known foundryman (name upon request), after trying many other makes of LEAD ordered a barrel of No. 522 EAST INDIA LEAD. He was so enthusiastic about the results from its use that he will buy no other. He writes: "Your LEAD has saved me time and money. My castings are the finest that I ever had. No pouring is hot enough to 'burn the LEAD in,' and when the casting is cool the sand peels off like an orange skin. I have no further use for a pickling vat."

STEVENS KING KORE KOMPOUND

Perfectly binds any kind of sand—salt or fresh water sands make no difference. It is peculiarly fitted for use with Canadian sands.

It is a black powder, light in weight—economical in use. It STAYS bound as long as required—releases the core from the casting without difficulty.

STEVENS CARBON BLACKING

A blacking that has a three-fold use. It may be used as a blacking for loam or dry sand molds. Second, it may be used as a core wash and cannot be dislodged from the core. Third, it is a splendid "shake bag" facing on green sand molds. A man reputed for his fine automobile cylinder castings uses this product in making of all of his cylinder cores. His cylinders are noted for their smoothness and evenness of the inside surface.

These are but a few of our specialties with which we can supply you—should you be so interested, we will mail you our 800-page Catalog of Supplies. This is really an encyclopedia of foundry information. You can have one for the asking.

WE HAVE BRANCHES SO THAT YOU CAN SECURE
YOUR SUPPLIES AT THE LOWEST POSSIBLE COST

WE would like you to understand the new McDougall Lathe. It is a machine of reserve strength and capacity. It can handle your "high speed" steel tools at their maximum speed. You get the benefit.

Note the headstock construction first. See the very wide bearing surfaces and massiveness. The whole machine from headstock to base is like a solid rock. We have done everything that will make this headstock right. It must wear. It must resist strain.

The big bearings are fitted with deep oil chambers and ring oilers. Your lathe is automatically protected against accidental wear and excessive loosening up of the bearings by the operator's omission to oil. Only when you get wear taken care of, have you a headstock which is able to resist strain. Its wide bearings are not only kept automatically in shop perfection, but they take the greatest strain a cutting-tool can give through the work and a spindle in high-carbon steel. The automatic oil device protects the quality of your lathe output by protecting the bearings, so chattering is impossible.

Look at the work of a McDougall Lathe some day. You will see a smooth, clean tool-cut, shining and bright. This shows the even feeding of the work from a firm headstock against a firmly-held tool.

The carriage and apron are non-springing. The action of the tool depends on the solidity of bearing given it by the carriage. This carriage is supported by full "V" bearings, and flat bearings as well. There can be no "lost motion" in the carriage, and none at the cutting edge of the tool.

The tool feed reads to thousandths both ways on the compound rest The automatic feed is of the safety type, so interlocked that your mechanic cannot operate both feeds (screw and rod) at the same time.

Here you have a clean cut from a solidly-held tool working against a solidly-held casting, in a lathe so protected by automatic oiling that it always maintains its accuracy and strength. You can adjust this tool to 1-1000 inch. You cannot break tool or work by accidental operation of both feeds at one time. No breakdowns.

Now look at the tailstock. It has a quick-acting sleeve lock device. This permits quick change of work. In addition the tailstock is secured to the webbed and non-springing bed of the lathe by four bolts with top adjustment. Both kinds of tailstock changes are easy and quick—they save workmen's time.

Take another look at this McDougall Lathe. See how well the gap is supported, and how deep the gap is. Though this is a gap lathe, it is as solid as a standard type, because the base is carried under the entire gap opening. Here you have a gap lathe without a single disadvantage of the gap opening and the deteriorated work it often causes.

Get a McDougall Lathe like this in your factory equipment. Its adjustability, speeds, capacity and practicability make it one of the most perfect machine tools. It is particularly economical where a variety of kinds of lathe work have to be done on a single lathe, because it is a quick-change machine.

Suppose you write us your problem. And, to-day, now. The McDougall lathe will raise quality and lower cost.

MODERN MILLING MACHINES

For Manufacturing Purposes

Belt Power sufficient to drive high speed cutters up to their limit.

Patent Locking Device binds **Knee** firmly to body.

Feed Screw always in tension, does not revolve, and is not splined.

Patent Dial Feed Box gives 16 feeds in geometrical progression; all gears hardened and run in oil.

Convenience of operation specially studied, enabling the operator to concentrate on quantity and quality of product.

PATENT BALL BEARING DRILLING MACHINES

with 1, 2, 3 and 4 Spindles.

Standard Spindle Drills up to 1 inch.
Geared Spindle Drills up to 1¼ inch.

Tests on Cast Iron:

1/4-inch hole, 1 inch deep, in 1 1/5 seconds.
3/8-inch hole, 1 inch deep, in 2 seconds.
7/8-inch hole, 1 inch deep, in 4 seconds.

Four to eight times as many holes drilled per hour as on an ordinary sensitive drill.

Spindle Speeds, 600, 900, 1370, 2050 revs. per minute.

Ball Bearings everywhere and absolutely dust-proof.

Only Needs to be Lubricated once a Year.

Machines sent on approval.

Send for Catalogues and prices.

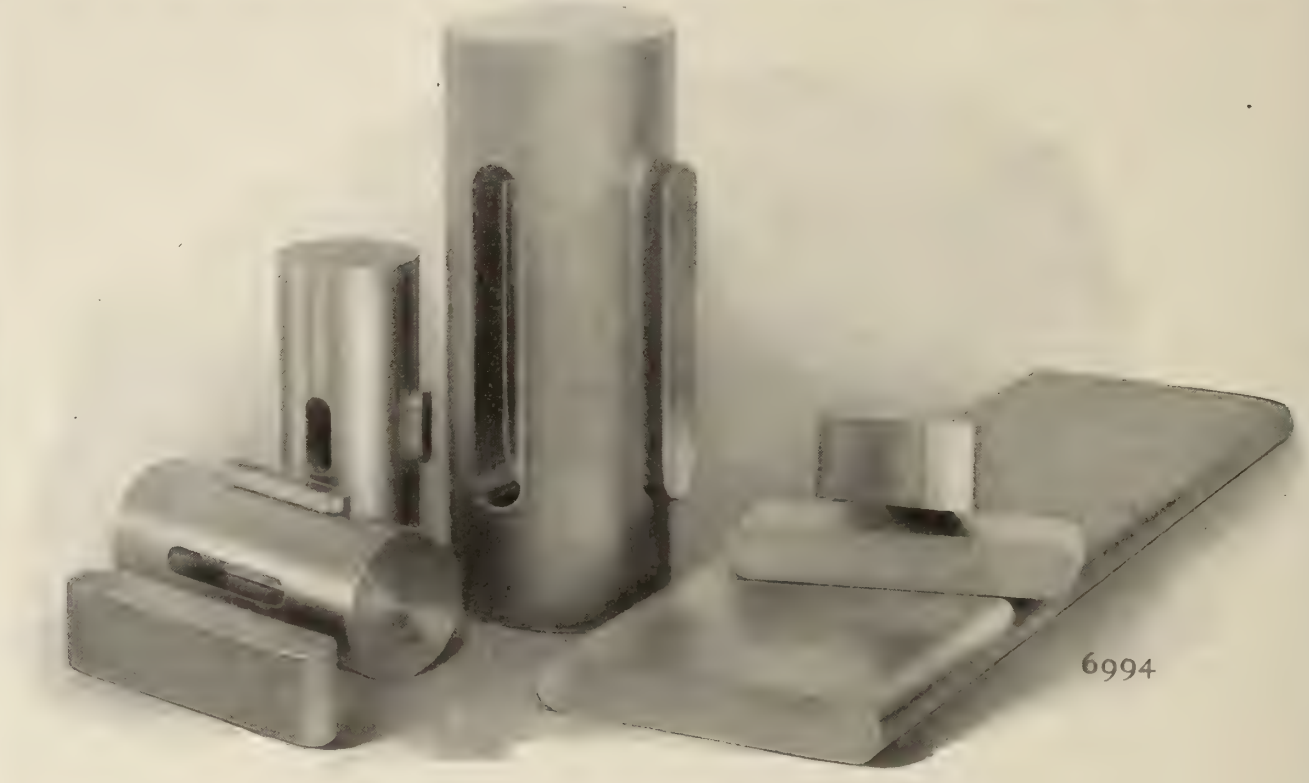
Rectangular Keys



By Far the Most Efficient and Economical—

1. They do not weaken the shaft.
2. They will not work loose.
3. Their shearing strength is practically equal to a solid member.
4. Two keys may be placed opposite each other on the shaft.

The Commercial Use of these Keys Made Possible by the Introduction of the

P. &. W. Spline Milling Machine

which rapidly mills the keyways in one simple operation, reducing the cost of cutting fifty per cent. or more.

Eliminates the drilling of starting holes. The "Fish Tail" cutters used are cheaper than end mills and remove metal much more rapidly.

Cost of Making the Keys a Minimum. The key stock is generally bright rolled in strips as shown, and sawed into keys. Rectangular cold rolled steel may be used by milling the ends round with a concave cutter and then sawing to desired thickness.

Pratt & Whitney Co. have adopted a standard of lengths and widths for rectangular keys, tables for which are included in catalog "Spline Milling Machine"—sent on request.

INQUIRIES ARE SOLICITED.

Facts About Ring and Surface Grinding Machines

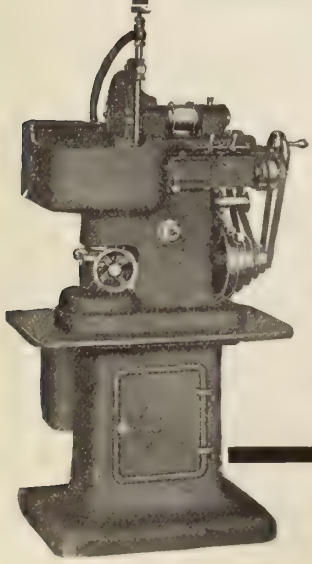
The machine—like the man—that can do everything, is usually a poor producer. That's why a "Single Purpose" machine, designed and built to do one thing and do it better than it can be done otherwise, and with greater profit, is the machine to use. How well we have succeeded in producing such a machine is best attested by the almost universal use of our Ring and Surface Grinders by automobile and gas engine builders in grinding their piston rings.

When you consider the importance of the piston ring in gas engine construction, it is easy to understand how poorly fitted rings will detract 10 to 15 per cent. from the actual power of an engine, because the fit must be as perfect **in the slots** as it is on the cylinder walls to utilize the full value of the explosive stroke. **This accuracy of fit was made possible, in a practical, commercial way, by the Heald Ring and Surface Grinding Machine.**

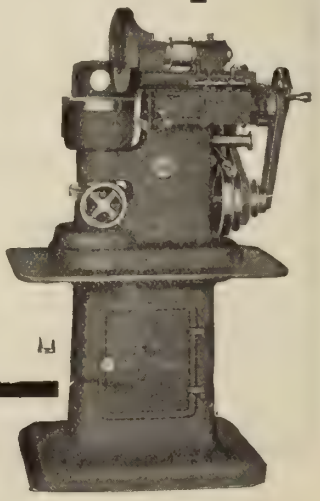
The value of the machine is not confined to piston ring grinding alone; it is adapted for grinding discs, thrust collars, saws and similar flat pieces. The magnetic chuck affords a secure and rapid means of holding and releasing the work, and angular adjustment is provided for grinding such work as milling cutters, saws, etc., which need to be thinner at the centre to give proper clearance.

Other special features are: Adjustable bearings for taking up all wear; micrometer adjustment for thickness of work; wide range of speeds for rotating work; variable cross feed to grinding wheel, etc.

Perhaps this or one of the other Heald Profit-making Grinding Machines is of interest to you. Let our Engineering Staff work out your problems with you.



There is an interesting, instructive Grinding Booklet too, that is free for the asking. If you knew what was in it, you'd want it.



THE HEALD MACHINE CO.

8 New Bond St., - WORCESTER, MASS.

ANSWER THIS!

WHY ARE "DETROIT" TWIST DRILLS

Sold on the broadest and most rigid guarantee?

Why are they making our sales larger to-day than ever before?

Why are they bringing ever increasing "repeat" orders?

BECAUSE

"Detroit" tools are all made with the understanding that the intelligent buyer and user of small tools demands implements that combine greatest accuracy with greatest wearing qualities.

The intelligent buyer of any small tool knows that it requires mighty good material and very exacting care on the part of a highly organized and highly efficient mechanical force to turn out thousands of "Guaranteed" Drills every day in the year with only an occasional poor one.

Send for Catalog "R." Just to show that you're open to conviction, select the tool or tools you'd like to try on some tough job. We'll make shipment with the distinct understanding that the test will cost you nothing unless it proves absolutely satisfactory.

Known by reliable Dealers everywhere. If your Dealer cannot supply you, write us direct.

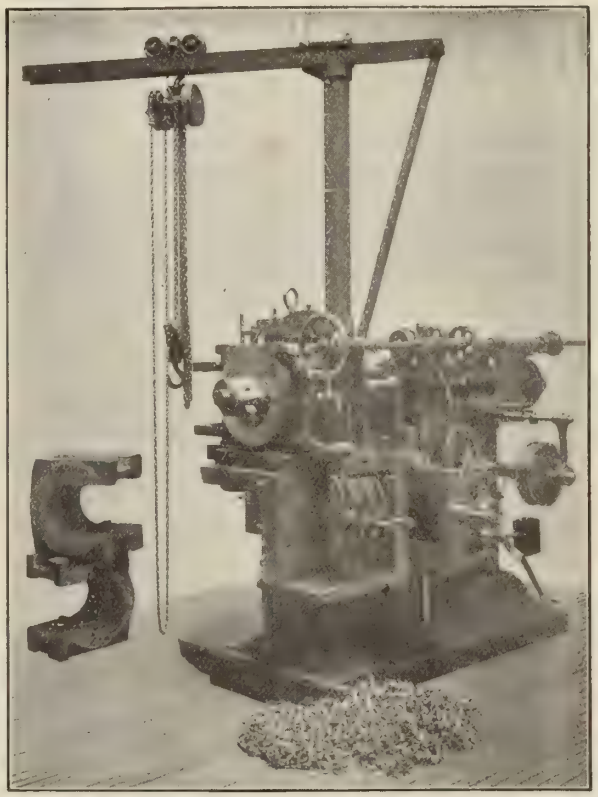
The Morton Draw-Cut Railroad Shaper



This shaper will crown and plane axle boxes, plane the brass shell to fit, and plane shoes and wedges at a saving of from 25 to 40 per cent. over ordinary methods. This machine is also equipped for doing a general line of shaper work.

For further particulars address

The Morton Manufacturing Company

MUSKEGON HEIGHTS, MICH.

Also builders of Cylinder Planers and a full line of Draw-Cut Pillar Shapers.

CINCINNATI UNIVERSAL TOOL ROOM MILLERS

Thirty-six holes ¼-inch diameter are spaced on the periphery of a 19-inch disk rigidly held on a 12-inch Index Head. They are first drilled, then bored, a trifle under size, and finally reamed to a plug gauge fit with a specially ground ¼-inch end mill. The error between holes is less than one thousandth (—.001 inch.) To get such results requires a miller that is accurate all over.

This is a good illustration of the best method of handling work of larger diameter than the index centres will swing. The swivel trunnions on our Dividing Head are large in diameter and fully protected in all positions, insuring permanency of alignment at any angle to which the spindle may be set.

Cincinnati Millers are as famous for their accuracy as for their productive capacity.

IN BUYING MACHINERY

Is it not worth something to you to know that you machinery is backed by the reputation of a large organization whose future depends upon your satisfaction—whose ability to satisfy is best shown by the enormous use of RAND machinery? Rand machines are used by the biggest users in the country. By men who have the time and methods for deciding upon the merits of a machine. This is the best proof of its superiority.

"RAND ORGANIZATION"

Our plant is devoted exclusively to the manufacture of pneumatic machinery and is one of the most modern and thoroughly equipped organizations in Canada.

Our representatives are specialists in the pneumatic machinery business and are equipped with complete information for advising on the installation of any of our product.

"RAND SERVICE"

Branch offices and warehouses are maintained within twenty-four hours' distance of any Canadian point. An ample stock of repair parts is kept for immediate shipment. A complete line of catalogs and pamphlets of information on all our lines is entirely at the disposal of our customers.

"RAND" service means efficiency as far as we can make it. Let us show you!

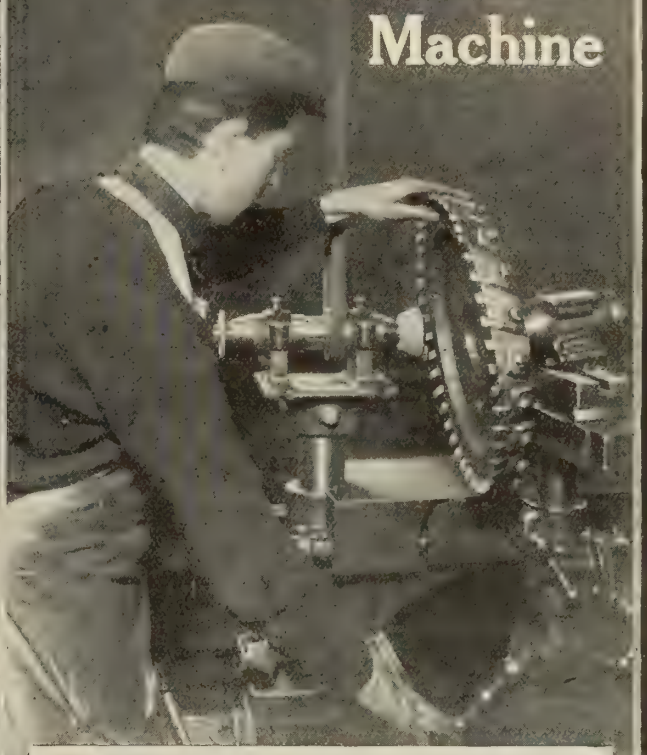
Selling Agents in Canada: Williams & Wilson, MONTREAL. General Supply Co. of Canada, OTTAWA and TORONTO.

An Aloxite Wheel Does Some Big Work On a Little Machine



ORDINARILY, the machine in question was used only on small work—it wasn't powerful enough to drive a slow-cutting wheel on a big job.

The operator put on a little Aloxite Wheel—it cut so fast and free that he is now running the machine far beyond its original capacity.

As an example, he backed off a 16-inch inserted tooth milling cutter—the wheel took off .003 of an inch from each tooth—never burned—held its shape and size—and made a mighty efficient machine out of a limited tool grinder.

Again it's the case of having the right wheel—an Aloxite wheel—in the right place. We have many more records of the merits of Aloxite wheels—write for our "efficiency booklet."

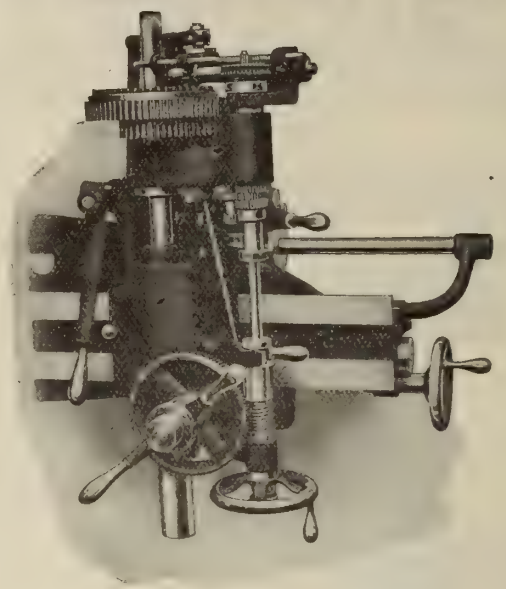
Canadian Agents—A. R. WILLIAMS MACHINERY CO. Toronto, Montreal, Winnipeg, Vancouver, St. John, N.B.

The combination positive and friction feed is among the superior features claimed for our

MUELLER RADIAL DRILL



This mechanism provides a positive feed for the spindle when high speed tools are in use and also permits of a friction feed being used when desirable, the operator easily changing from positive to friction feed by slightly releasing the split bearing of the upper worm wheel. Eight (8) changes of feed to each change of spindle speed are provided for and are instantly obtainable.

The story of the Mueller Radial Drill is very interesting.

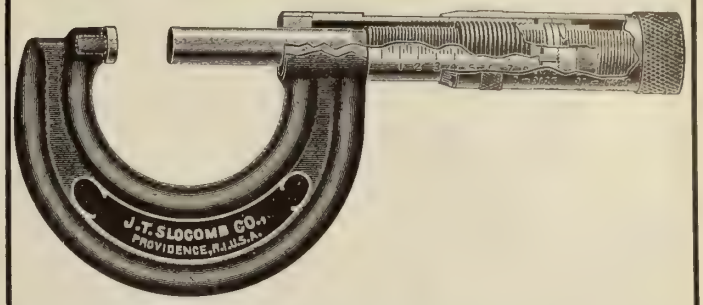
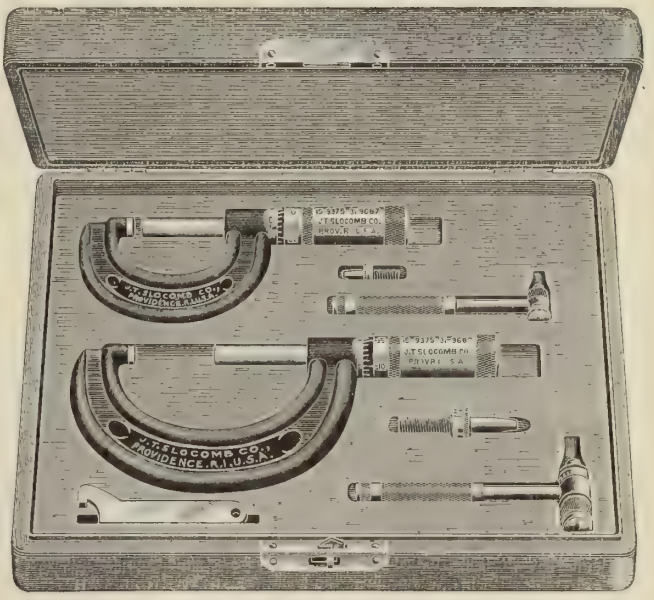
"The Longest Lived Micrometer that can be purchased."



The above is what was written us by the Superintendent of one of the largest automobile factories in the United States.

He had tested tools for many years and knew why it was to his benefit to use this kind. You would come to the same conclusion if you would give them a trial. Why not do it.



Set No. 106.

It's the same with the new inside micrometers for ½ to 2 inches. They have long handles which permit measuring entire depth of hole. If you haven't seen them, you should, as they are particularly valuable for slotting, grooving, boring and all kinds of internal work.

OUR NEW CATALOG NO. 13C.

The Geometric Threading Machine

is turning out a large amount of screw threads —work that cannot be done to advantage on the usual screw machine, and work that cannot be done satisfactorily in any other way.

The Die Head with which this machine is regularly fitted has a range of cutting from one-quarter inch to three-quarter inch diameters inclusive.

Where fine pitch threads are to be cut on larger diameters, the machine can be fitted with a Die Head to take care of the work.

The chasers, from time to time, can be renewed at slight cost as they become worn.

Do not confuse our Machine with the usual Bolt Threading Machine.

Send for Descriptive Booklet.

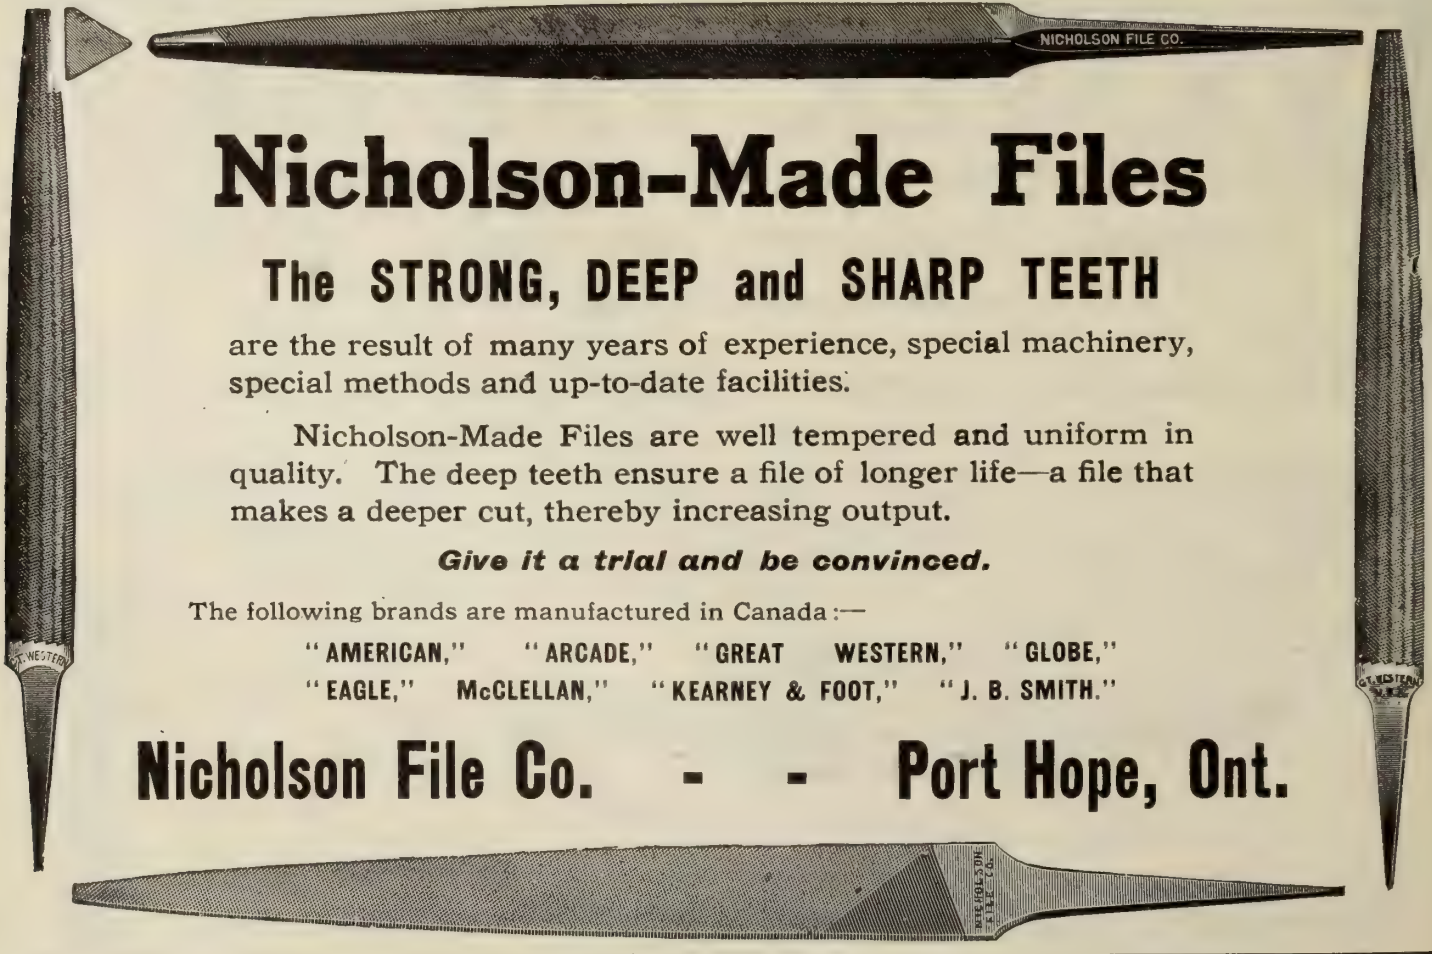
NEW HAVEN, CONN.

Canadian Agents: Williams & Wilson, Montreal; A. R. Williams Machinery Co., Toronto.



Nicholson-Made Files

The STRONG, DEEP and SHARP TEETH

are the result of many years of experience, special machinery, special methods and up-to-date facilities.

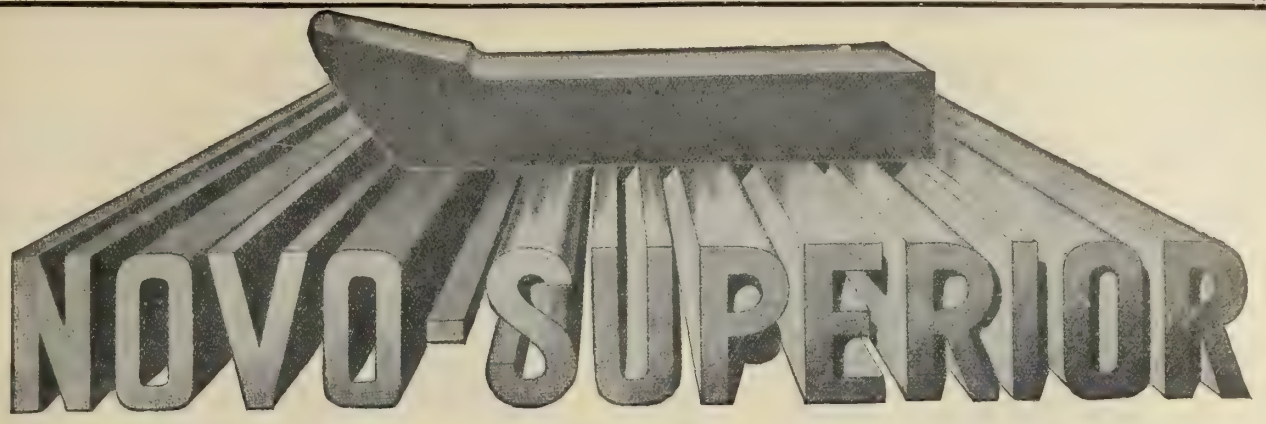
Nicholson-Made Files are well tempered and uniform in quality. The deep teeth ensure a file of longer life—a file that makes a deeper cut, thereby increasing output.

Give it a trial and be convinced.

The following brands are manufactured in Canada:—

"AMERICAN," "ARCADE," "GREAT WESTERN," "GLOBE,"
"EAGLE," McCLELLAN," "KEARNEY & FOOT," "J. B. SMITH."

Nicholson File Co. - - Port Hope, Ont.



High Speed Steel Has a Solid Foundation In a Name That Means Something

Cutting speed attained on cast iron: Roughing cut, 140 ft. per minute—finishing cut, 210 ft. per minute.

In NOVO SUPERIOR you secure a materially increased speed over the high speed steels now in use, the highest quality, greatest toughness, longest life (3 times that of any other) and exceptional ability to cut very hard materials. The cutting edge retains its sharpness from 3 to 4 times longer than other high speed steels. Hardens in oil, air or water, and is now carried in stock in our warehouse in all current sizes, flat, squares and rounds; annealed and unannealed.

Drills and Grinders for every purpose.

Why Didn't We Protect Those Windows, too, With Fenestra Sash ?

What *water-tightness* is to an ocean liner—
What *burglar-proofness* is to a bank—
What *strength* is to a sky-scraper—
Fireproofness is to a modern industrial building.

It would seem hardly less logical to handicap the watertight compartments of a ship with frail partitions, to offset the 3-foot cement floors of a vault with a wooden trap-door, or to construct a Singer building on a doubtful footing, than it is to build a modern factory of fire-proof construction, equip it with sprinkler-systems, fire-doors and fire-alarms, and then to demoralize the whole chain of expensive and otherwise carefully planned fire-protection by tolerating the weak link of wooden sash.

Scientific factory construction relegates wooden sash to the day of clapboard walls, plank floors and shingle roofs.

Where else can you reasonably class them ?

FENESTRA FIRE PROOF SASH

glazed with ordinary wired glass is positively the last word in fire-resistance as applied to windows.

Common sense dictates that.

Actual fires have proven it beyond question. In a fire at Stoneham, Mass., in September, a building equipped with FENESTRA SASH was practically surrounded by a burning varnish factory. Reglazed after the fire, the Sash were as good as new. Photographs on request.

Remember, too, that FENESTRA SASH also *light* and *ventilate* a building better than any others. They're made to suit individual needs.

If you are interested in the planning or construction of a building where *light, fresh air,* and *fire protection* are essentials, let us send you our "Fenestra" Catalog.

Rot-Proof Air Hose for Use and Abuse

You save money when you buy Goodyear Air Hose for the reason that it lasts longer—gives more service than any other air hose manufactured. This is because we make it by a special process that renders it impervious to the attack of compressor oil—the ruinous agency that rots all other air tubes.

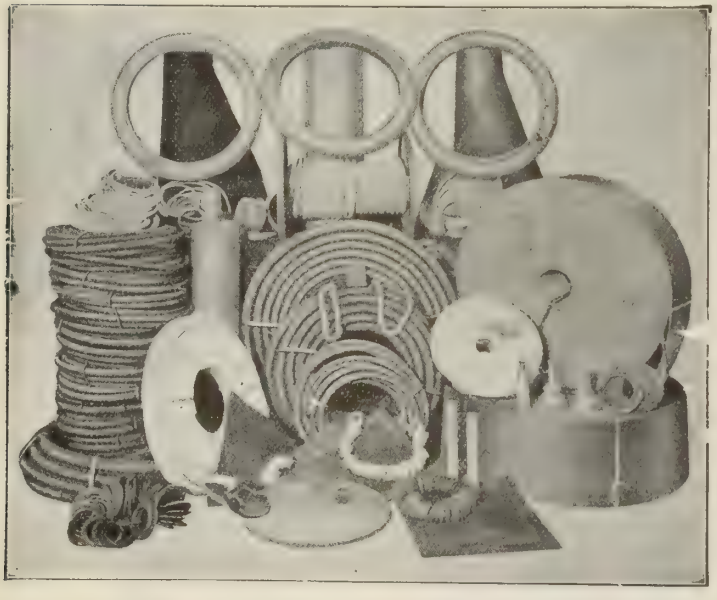
GOODYEAR

Air Hose

The Economical Hose for all Pneumatic Uses

The great difficulty with all rubber air hose is that due to the action of the oil that comes from the compressor. This oil rots the inside of the tube. Then it chips off, clogs up the throttle and before you know it your tube is useless and your tools need repairs.

All this is now overcome. After long and costly experimenting our experts have now perfected a tube made of a special compound that resists oil and the heat developed by air compression. It neither chips, hardens nor cracks. And when other hose begins to *play out*, this hose is as *good as new*.



A Few of the Lines We Manufacture

Goodyear Air Hose is further protected from cuts and bruises by a heavy canvas jacket. This brings an extra thick ply of rubber between outer canvas cover and first inner layer of fabric, resulting in a hose of unequalled strength and toughness.

Can be supplied with the further protection of wire winding or Marlin wind. Made in three grades. Used in practically all mining operations, steel construction works and boiler works—wherever pneumatic tools are in use.

Write to-night for catalog and prices.

The flame of a powerful blow-torch—which is intense enough to even melt iron—will not burn J-M Asbestos Ready Roofing when held on *one spot* for nearly an hour. Nor will it set fire to boards underneath. This has been proved by impartial tests made by Fire Chiefs and City Council Representatives of many large cities.

J-M Asbestos Roofing is absolutely fire-proof because its base consists of several layers of pure Asbestos Felt. And Asbestos, you know, is the fire-proof, practically indestructible, mineral used in gas grates, stove mats, theatre curtains, etc.

These layers of Asbestos (stone) Felt are firmly cemented together with genuine Trinidad Lake Asphalt—that wonderful mineral cement which, in asphalt pavements, stands the grinding of wheels and pounding of hoofs for thirty to forty years.

J-M ASBESTOS ROOFING

is composed of all minerals. Not a particle of perishable material in it. Because of this mineral or stone construction, J-M Asbestos Roofing is also rust-proof, rot-proof and acid-proof. And, like all stone, it never needs coating.

No other ready roofing gives a building such absolute fire protection. None other lasts so long with so little attention. J-M Roofing is still in good condition on many buildings after nearly a quarter of a century of service.

Our nearest Branch will supply you with J-M Asbestos Roofing if not obtainable at your dealer's.

Write nearest Branch now, for our handsomely illustrated Catalog No. 303.

BULL RINGS

Perhaps you have not thought of Magnolia Metal in connection with Bull Rings. It seems to be just the thing. It is also good for piston and stem rod packing.

MOBILE LIGHT AND RAILROAD COMPANY.

Mobile, Ala., January 12th, 1912.

GENTLEMEN.—In answer to your inquiry of January 2nd, will state that the Magnolia Metal put in our Bull Rings two years ago is giving perfect satisfaction. The metal has worn about 1/32″ on the bottom in that time. The ring is 58″ in diameter and 11″ of bearing surface. Two days were used in the job of removing the ring, preparing it for filling and turning it in a lathe to fit cylinder after it was poured. If the above is any use to you, you may use it any way you like.

Respectfully, C. MANKER,
Engineer Power Station.

The method employed in applying Magnolia, as described by Mr. Manker, will be sent to anyone desiring the information.

PUMPS

The superior excellence and splendid results shown by

"FAIRBANKS-MORSE"

pumping machinery are largely due to the fact that for many years we have manufactured Hydraulic Machinery of all descriptions. We are therefore able to build pumps which are properly designed and adapted to every-day use. This is of the greatest importance in a first-class pump, for the usefulness of an engine may be lost if the pumping machine is badly designed.

You will get all these important features when you purchase a "FAIRBANKS-MORSE" pump.

Let us solve your pump problems.

The Western Dry Dock & Shipbuilding Co., Port Arthur

By J. H. Williams

A description of the dry dock and shipbuilding equipment of a company who recently commenced operations, and are already obtaining a good share of orders. The plant forms one of Port Arthur's principal industries and gave steady employment to about 350 men throughout last winter.

WITH the establishment of the Western Dry Dock & Shipbuilding Co., Ltd., at Port Arthur, Ont., Canadian inland shipping has been supplied with one of its most pressing needs,—viz., dry dock accommodation at the head of Lake Superior. The company which is an off-shoot of the American Shipbuilding Co. has a fully equipped shipbuilding and repairing plant of the most up-to-date description, and its organization is now complete,—in fact the first ship built on the plant is almost ready for launching.

The site occupied by the company's dock and shops has an area of about 100 acres, so that ample space is provided for future extensions when required.

The Dry Dock.

The dry-dock was completed at the end of November, 1910, and presents several features of interest. It was designed by Mr. A. V. Powell, of Chicago, and constructed by the Canadian Stewart Co., Ltd. Much thought was given to the question of its dimensions, with a view to providing for larger boats than those in common use on the Great Lakes at the present time. Finally, a length of 700 feet was decided upon. The largest lake freighters at present in use do not exceed 610 feet over all, and experts seem to be agreed that this length cannot be much increased, unless accompanied by an addition to a depth that would render such boats unable to use most of the existing harbors. However, a dock length of 700 feet allows for any freak boat that may be built in the future, and will also accommodate two vessels of a size in common use at present.

The dock is of solid concrete and rests upon a rock foundation. Fig. 5 shows a general view of it, while Figs. 2 and 3 show sections and plan respectively. From these it will be seen that the width at the top is 98 feet 8 inches, and that the depth of water over the portal side is 16 feet. The gate or caisson is of steel, its leading dimensions being given in Fig. 4. It is fitted with five 30-inch flooding valves, and is emptied by a small steam pump situated in the interior above the flood line and provided with steam from a boiler on the dock side.

The dock itself is emptied by two 30-inch centrifugal pumps driven by 200 H.P. direct connected vertical motors. There is also an 8-inch pump of the same type, driven by a 30-H.P. motor; this takes care of the drainage. All three pumps were supplied by the John

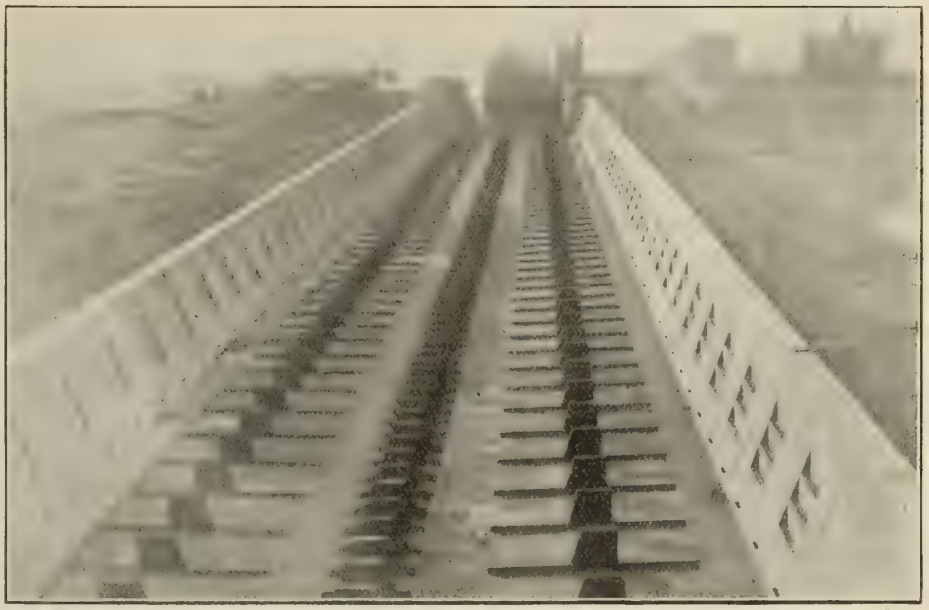

Fig. 5—General View of Dock.

Fig. 1—Entrance to Dock. This photograph was taken before the shipbuilding gantry was erected.

Inglis Co., Toronto, while the motors are of Westinghouse make.

Building Berth.

There is at present one building berth situated on the west side of the dock. It is 700 feet long and is served by a 10-ton electric gantry crane supplied by the Wellman, Seaver & Morgan Co., of Cleveland, Ohio. The clearance from ground to underside of crane is 56 feet. On the west side, the gantry is of steel, while on the side next to the dock it is of timber construction to facilitate removal previous to launching—all boats being side launched into the dock. Compressed air headers run the full length of the building berth, the various pneumatic tools being coupled thereto by flexible connections in the usual way. Both sides of the dock are similarly equipped, as are also the various shops throughout the plant.

It is the intention in the near future to construct a second building berth on the opposite side of the dock.

Ship Construction Equipment.

The punch shed stands in line with and at the head of the dry dock. It is a steel frame building of two storeys, 250 feet long by 160 feet wide. A centre row of steel columns divides the lower floor into two bays, each of which is served by two Pawling and Harnischfeger 7-ton electric traveling cranes. The runways for these cranes extend out beyond the north end of the punch shed, so that they may handle material in the stock yard which is there located. The stock yard is also served by a standard gauge track; so that material passes from cars to punch shed and thence to the building berth with a minimum of handling. Generally speaking the plate work is all done in the west bay of the punch shed, while the east bay is given over to shapes. All machines are driven by individual motors. Those in the west bay include a 32-feet plate edge planer by the John Bertram & Sons Co., 16 feet heavy plate bending rolls by Wickes Bros., two wall radial drills, and eight punches and shears by the London Machine Tool Co., and Hilles & Jones. In the east bay are found the lighter punches and shears, and a bending machine for shapes, supplied by the John Bertram & Sons Co. The motors and gearing of all the punches, etc., are enclosed in substantial wooden housings, to which the motor controllers and switches are affixed. Each machine is served by a 3-ton bracket crane swung from the adjacent column. In annex at the north-east corner of the punch shed are housed the slabs and two flanging furnaces.

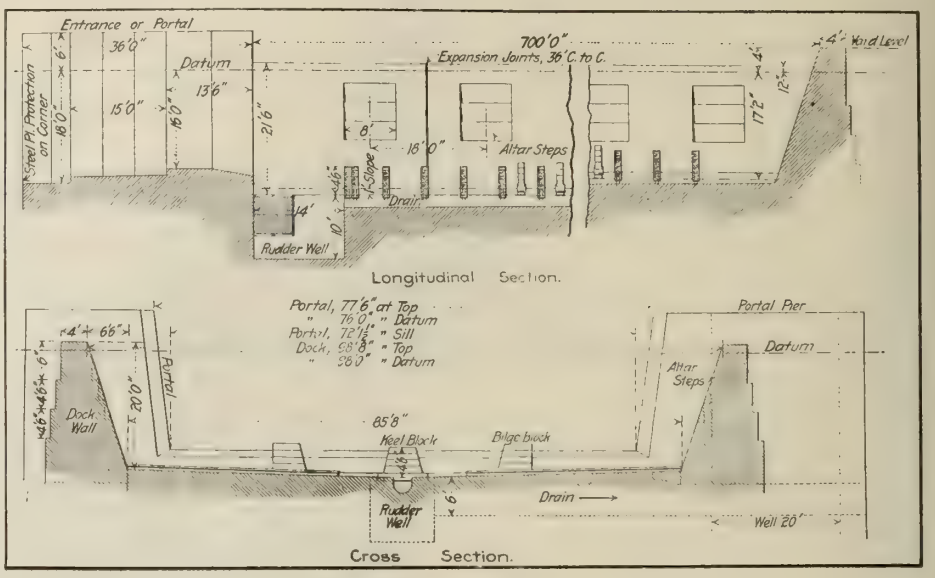

Fig. 2—Sections of Dock.

The mold loft is situated immediately above the punch shed and is of the same area as the latter. It is excellently lighted and contains the usual equipment for making the marking off templets.

The Boiler Shop.

This shop is well equipped with the most modern tools for the convenient assembling of boiler and tank work of every description. It is a self-supporting steel frame building with brick walls and a cinder floor, served by standard gauge tracks. The shop is 180 feet long by 90 feet wide and is divided into three bays, of which the centre one is used for assembling purposes, being served by a 20-ton electric traveling crane. All the machines have individual motor drives and are of the most modern construction. Amongst them are included two heavy punches (60-inch throat) and one 48-inch throat shear, by the London Machine Tool Co.; 36-inch throat punch, 18-inch throat shear and horizontal punch by Long and Allstater; one horizontal triple-head Dallett drill, each head being driven by individual motor; one Bertram 4-spindle drill; one radial wall drill and one fixed ditto for drilling large plates. Bolts, stays, etc., are screwed either on an Acme double-head 2-inch bolt cutter or on a 4-inch machine of the same make.

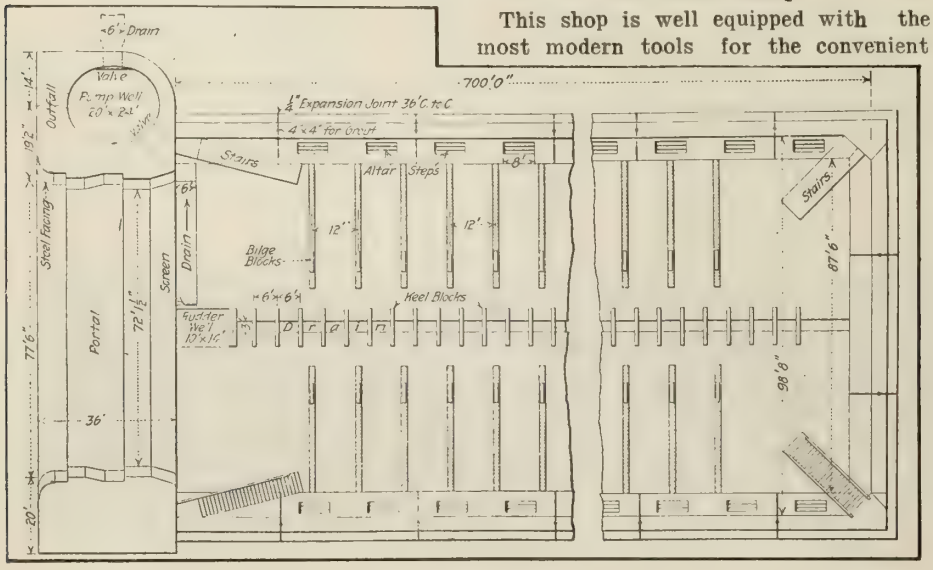

Fig. 3—Plan of Dock.

The west bay is devoted to the petty stores and to the flanging and riveting departments. There is a 150-ton hydraulic sectional flanging press served by a 3-ton hydraulic jib crane. Here all flanging, upsetting and dishing is done. The furnace serving the press is 18 ft. long, by 10 ft. 6 in. wide, and is heated by coal fires; draft being provided by a steel stack 42 inches diameter and 60 feet high. Tube sheets, etc., are heated for flanging in a long open fire, which enables 11 feet to be heated at one operation.

Whenever possible, riveting is done on a 125-ton fixed hydraulic riveter of 10 ft. 6 in. gap. The rivets are heated in a small coal fired rivet furnace on the platform. The accumulator for the riveter and flanging press has a 9-inch ram and a 12 ft. stroke, the working

pressure being 2,000 pounds per square inch. To avoid trouble in winter, oil is used instead of water and is forced to the accumulator by a Deane $2\frac{7}{8}$x12-inch triplex pump driven by a 70 H.P. Westinghouse motor. The accumulator, riveter and flanging press were supplied by the R. D. Wood Co., Philadelphia. Blast for the rivet furnace and open fires is provided by direct coupled motor driven fans.

On completion, all boilers are tested by a motor driven Deane $2\frac{1}{2}$x5-inch triplex pump, the line to the boiler being provided with a safety valve which may be set to any desired test pressure.

Forge and Machine Shops.

These two departments are at present occupying temporary wooden buildings; but it is the intention to build permanent shops for them this year. The blacksmith shop comprises five forges and one 800-lb Bertram hammer, which is operated by air.

boring the cylinders of tugs, etc., when in position.

The machine shop has a well equipped tool store, behind which is located the general material store for valves, pipe fittings, bolts, etc. The upper end of the shop is at present given over to the pattern makers and ship carpenters, and is fully equipped with the necessary wood-working machinery.

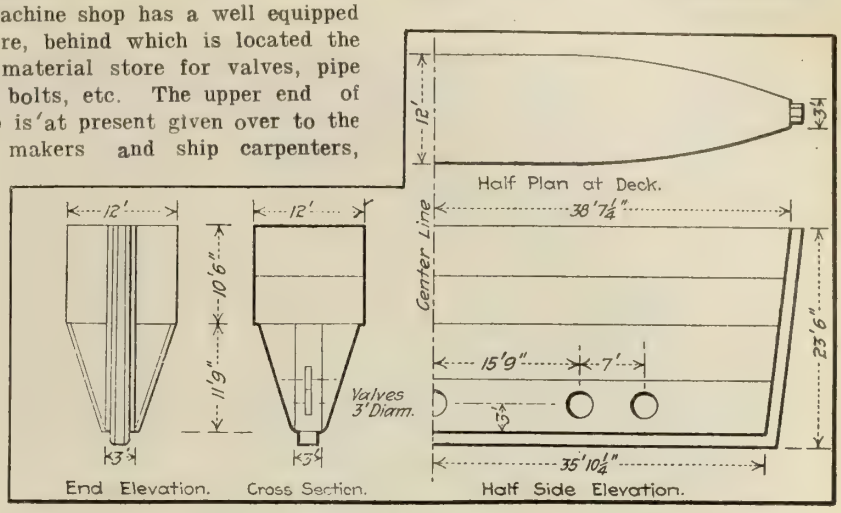

Fig. 4—Dock Gate or Caisson.

Fig. 7—General View of Boiler Shop.

Most of the machine shop equipment is of Canadian manufacture, with individual motor drive. The John Bertram & Sons Co. supplied a 60-inch shafting lathe, taking 22 ft. 4 ins., between centres; 26 in. engine lathe, taking 10 ft. between centres (motor controlled from carriage); 24-inch shaper; and 48-inch radial drill. The London Machine Tool Co. is represented by a 36 in. x 12 ft. planer, with side head; 10-in. engine lathe with geared head; and 24-inch slotter. There is also an 18-in. engine lathe by the Canada Machinery Corporation and a group drive, comprising one 2-inch and one 8-inch Bignall & Keeler pipe threading machines, Acme bolt cutter, 18 in. engine lathe by Schumacher & Boye, and a double emery grinder.

The company have recently constructed a motor driven boring bar of 10 inch. x 12 feet capacity, for boring out stern tubes, and also have a hand operated bar—6 inches x 10 feet capacity—for re-

Power House.

The power house is situated near the entrance to the dock and contains two motor generator sets each of 250 H.P. generator capacity. The generators are driven by 30-inch belts from 350 H.P. motors taking city current (A.C.) at 2,200 volts. Compressed air is supplied by a Rand air compressor having a capacity of 1,200 cubic feet of free air per minute. This is belt driven by a 200 H.P. motor and delivers air at 100 lbs. pressure. There is an exactly similar compressor in the machine shop.

Water service throughout the plant is provided by a Deane motor driven two-throw pump taking water from Lake Superior. Provision is also made for using city water if required; the latter being always used for drinking purposes. The shops are lighted by enclosed and flame arc lamps, while the building berth and dock are wired for portable incandescent lamps or extension cables.

Work in Hand.

The company are just completing their first vessel. This is the S.S. Hamiltonian, a steel vessel built for the Norcross Bros. Co., Toronto. She is 257 feet long over all, $42\frac{1}{2}$ feet beam and $26\frac{1}{2}$ feet molded depth, being of the

Fig. 6—Punch Shed and Gantry.

maximum size that will pass through the Welland Canal. She is a package freighter and is equipped with a full complement of winches, derricks, etc., for handling this class of goods. Her hull is constructed with longitudinal framing on the Isherwood system, for which the Western Dry-dock and Shipbuilding Co. hold the sole Canadian rights for the Great Lakes. She has a single four-bladed sectional propeller, driven by a 3-crank triple expansion engine with cylinders 18, 24 and 48 inches diameter by 40 inches stroke. The jet condenser is fitted with an Edwards air pump. Steam at 175 lbs. pressure is supplied by two Scotch marine single-ended boilers, 11 feet 6 inches in diameter by 11 feet 6 inches long. Each boiler has two Morrison suspension furnaces, and induced draft on the Ellis and Eaves system is fitted.

Fig. 8—Centre Bay of Boiler Shop.

The hull, being built on the Isherwood system, will increase her cargo-carrying capacity about 10 per cent. as compared with a vessel of the same size having the usual system of cross framing. In passing through the canals, vessels frequently have considerable side wind to contend with, and are sometimes driven against the stone locks, corrugating the plating and breaking off rivet heads immediately above the tank top. Water leakage results and damages the cargo. To overcome this trouble the Hamiltonian's tank, from boiler room to forepeak, is carried 9 feet up the sides. Thus any leakage resulting from sheared off rivets will go to the double bottom instead of into the cargo.

Orders lately received include a steel stern wheel steamer for the C.P.R. service on the Kootenay Lake. This vessel will be 200 feet long between perpendiculars, 40 feet beam and 8 feet deep. The engines will be tandem compound with cylinders 16⅜ and 35⅜ inches diameter by 96 inches stroke. Steam will be generated by a locomotive type boiler 8 feet in diameter by 28 feet 4 in. long with working pressure of 200 lbs. per square inch.

Another important order lately received calls for a large steel passenger vessel for the Northern Navigation Co. on the same lines as the Hamonic. The vessel will be of steel, 385 long, 52 feet beam and 28.75 feet depth. She will be fitted with a four-cylinder triple expansion engine; steam being furnished by four Scotch type boilers. She will cost about $750,000, and it is planned to have the launching take place in June, 1913.

Fig. 9—Exterior of Boiler Shop.

Fig. 10—Waterfront and 70-ton sheer legs. Boiler shop, punch shed, etc., in background.

A BIG POWER PLANT SAVING.

The analysis of boiler compounds as an end in itself presents little to excite enthusiasm, says Arthur D. Little, president of the American Chemical Society, but when such analyses are made the means of saving $3,600 a year in the power plants of a single company they take on a new and larger aspect, not only in the mind of the chemist, but in the mind of the chemist's client.

DEVELOPED WATER-POWERS.

As a result of investigations undertaken by the Commission of Conservation, it has been ascertained that there are 1,016,521 horsepower developed from waterpower in Canada.

Prominent Features of Forge Practice in English Shops, II.

By Joseph Horner

The writer is well and favorably known through his contributions to the editorial columns of the leading technical journals of Great Britain and the United States. Concerning Canada, he is no stranger, having on previous occasions furnished highly instructive information to readers of Canadian Machinery on important developments in mechanical engineering practice. The subject of the present series of articles will be found extremely interesting, enabling, as it does, a close comparison between British and Canadian methods to be made, and perhaps profitable hints extracted.

SMALL forgings made in large quantities are now probably hardly every produced by hand methods, but are stamped wholly in dies. There are two classes of shops dealing with this

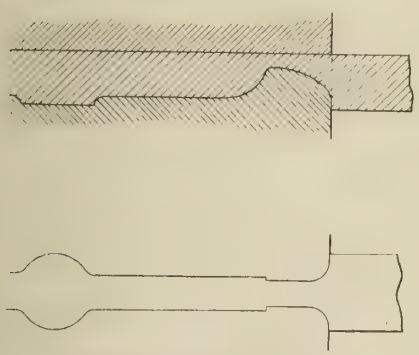

Fig. 13—Forge Practice.

kind of work—those which make their own and those who buy out. A number of big firms now supply stampings to the trade, and where the quantity required is only moderate, it is cheaper to buy than to lay down a plant. Some firms again have a stamping department as an auxiliary to their ordinary smithy. Such a system once introduced inevitably grows, just as does that of machine moulding in a foundry, because the possession and accumulation of dies tends to standardization of similar parts. Little differences in dimensions which have no justification in point of strength or appearance are obliterated, and a few averaged sets of dimensions supply the place of a heterogeneous and perfectly useless lot of variations evolved from the fancy of the draughtsman. Moreover, as the numbers which are stamped increase, a better class of dies is evolved, the cut steel does taking the place of cast-iron for attachment to tup and anvil. This practice of drop-forging is now very extensively adopted. A few years since it was seldom seen outside the small arms, cycle and similar factories, and a few firms who made a specialty of small mechanisms; excluding, of course, the shops which supplied stampings to the trade. Now, it has become familiar in many general engineers' establishments where specialities are handled, being favored and fostered by the pressure of competition, the increasing specialization of manufactures and the necessity for interchange ability.

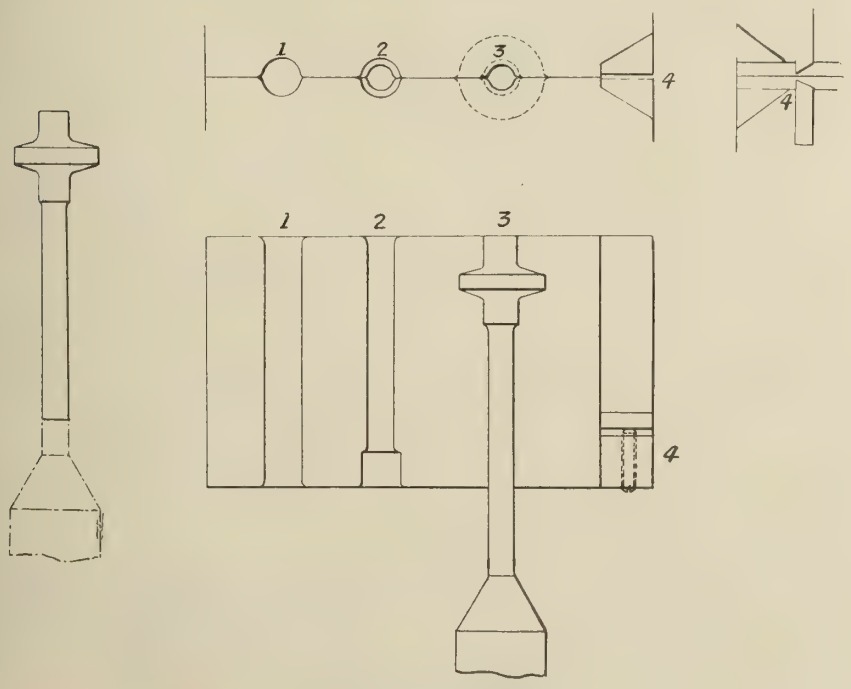

Fig. 12—Forge Practice.

Power Hammer Improvements.

Improvements in power hammers have, however, been greatly contributory to this result. The old belt and board drop hammers, long familiar in the Birming-

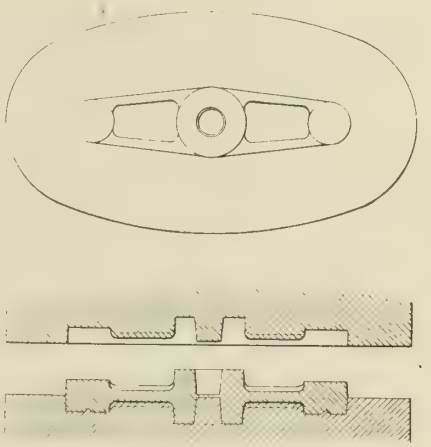

Fig. 15—Forge Practice.

ham district, operated by foot or hand of the workman, have been succeeded by better English and American forms. The American-Bradley cushioned hammer has had a large and appreciative patronage, and the English-Brett lifter hammer has been extensively installed in many English and Continental shops.

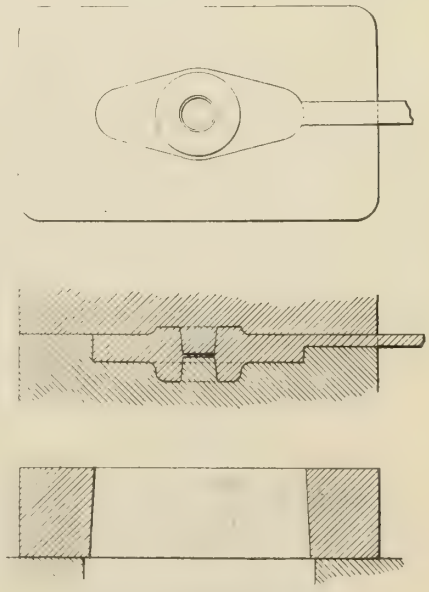

Fig. 14—Forge Practice.

These, and the types of which they are broadly representative, are operated by steam or compressed air, and are varied in design to suit all classes of forgings. They deliver a rapid succession of blows, the frequency of which is entirely under control of the attendant, and they can be rendered automatic at will, working slowly or quickly, with a predetermined height of lift. The metal is

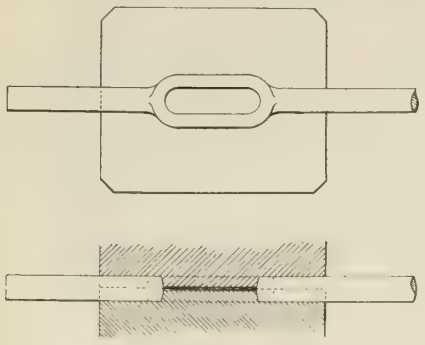

Fig. 16—Forge Practice.

consolidated and the surface left highly polished. Steel is used more extensively than iron, because no trouble occurs with direction of fibre. No forgings made thus are of large dimensions.

The very general substitution of mild steel for wrought iron has been favorable to the growth of stamping in dies. In iron forgings the direction of the fibre is of so great importance that forgings which involve much curve-hooks, forked ends, eyes, loops and similar articles must be bent preliminary to the work of stamping, and this bending in many cases also involves a weld. In mild steel, however, all such can be stamped from solid lumps, because there is no fibre causing weakening when cut across. Large quantities of odd ends of steel are used in this way, and which as scrap would fetch little.

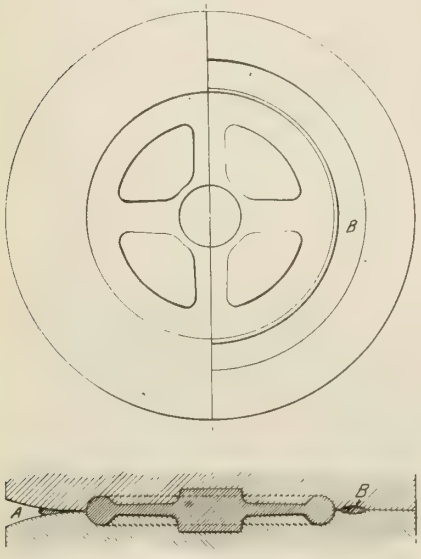

Fig. 17—Forge Practice.

Scope of Drop Forging Practice.

Drop-forging practice must be controlled by the bulk or mass of the particular work done and by its character. The largest proportion comprises what may be included under the term lumps, which are produced from solid masses; none of which are of very large dimensions. Lumps or single solid masses are forged from bars of suitable cross sectional area. These include numerous small parts for engines, cranes, machine tools, machines and small tools of various kinds. On these no preliminary work is done, but the bar is heated and set at once in the dies, roughed, finished and stripped at one heat. In making articles of small dimensions, two, and sometimes three forgings are done at one heat and cut off. Sometimes odds and ends are utilized, in which case a porter bar is frequently welded on by which to hold the forging. The simpler the forging the more rapidly can it be produced. The term, simplicity of a forging used in this sense, does not convey quite the same meaning that it would to a man working at the anvil. A forging may be intricate in the sense of being of irregular outline without entailing any extra work or trouble in stamping it. It is not simple in this sense, if more than one set of dies has to be used, if setting, after forging, has to be done, or if a loose piece has to be inserted to punch a hole, or to form the hollow of a fork, and so on.

Class of Forgings.

The simplest forgings are those which are wholly circular, though a rectangle in continuation of the cylindrical portion matters little; the reason being that the work, when circular, is rotated in the dies between each blow, Fig. 12, and the required dimensions and shape are soon obtained. Such forging is usually begun and completed between one pair of dies, but in successive stages; reducing from larger to smaller recesses and thus easing the work. Even though one part is much larger than another, as in a valve and its stem, Fig. 12, forged solidly, upsetting is not done, neither is welding, any of which methods might be adopted at the anvil; drawing down only being practised. This is done in stages, usually in one pair of dies only, but sometimes in two pairs on adjacent hammers, the finish being imparted in the final recesses of the exact shape, Fig. 12. Here, the recesses for the successive operations are marked in order, 1, 2, 3, 4. This is work of the kind which has no fin, and, therefore, requires no stripping because it is rapidly rotated, and the fin which begins to form is suppressed at the successive turns. In the dies for such articles, keen edges are not left, but the edges instead are slightly convex, Fig. 12. Again, the recesses in the dies need not be semicircles, nor the faces close together when the work is down to size. Work produced thus has a fine and glossy surface finish, suitable enough for many purposes without tooling of any kind. Cutting off is usually provided in the dies for shapes of this

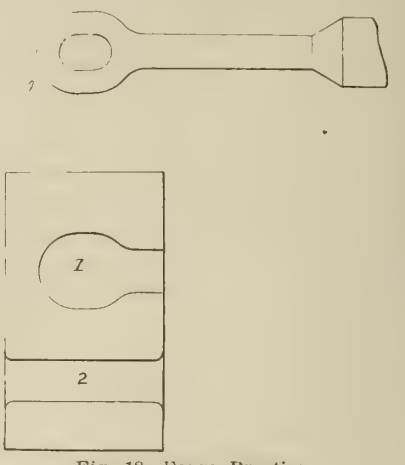

Fig. 18—Forge Practice.

kind, Fig. 12 (4). In others, the finishing grooves are terminated in a narrow neck, Fig. 13, which reduces the area or diameter there, so greatly, that the forging is practically severed.

Those forgings which are flat cannot be turned about in the dies. These can often be gradually broken down in two or more recesses or in some cases a forging can be roughed and completed in one operation as happens where there are no great discrepancies in adjacent dimensions, Fig. 14. A fin, however, is unavoidable, and the rapid removal of this requires the aid of the stripping die, seen in the lower part of Fig. 14.

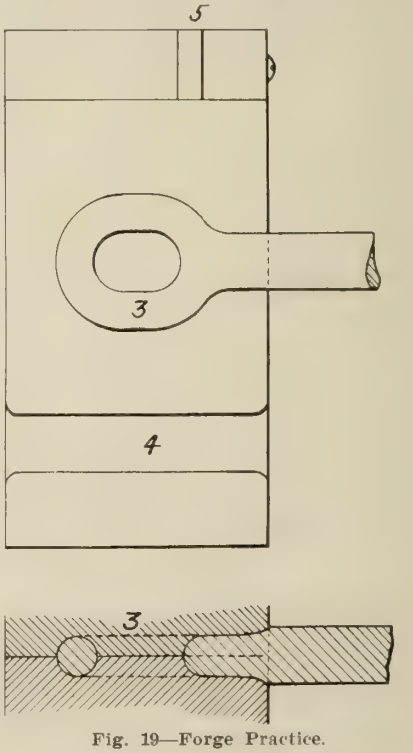

Fig. 19—Forge Practice.

This is sometimes in one with the forging die adjacent, but is more usually distinct from it on the same or a separate anvil. The profile of its opening is exactly that of the forging but tapered downwards. A slight hammer blow drives the forging, laid redhot on the stripper, through the latter, and removes the fin cleanly and easily.

When holes are made in die forgings they are usually produced with punches which are part of the dies, Figs. 14, 15, and 16, instead of by using a separate punch as is generally done at the anvil, and in dies which simply supplement and finish anvil work as illustrated in the last article. If the forging is shallow, a single punch suffices. If of fair depth, two are preferable in top and bottom dies. They must be well tapered and not quite meet at the centre; the fin left being driven out with a drift.

When a considerable quantity of fin is formed, the stripping die is necessarily used. It is convenient, but when there does not happen to be room on one anvil, or no adjacent hammer, the fin may be

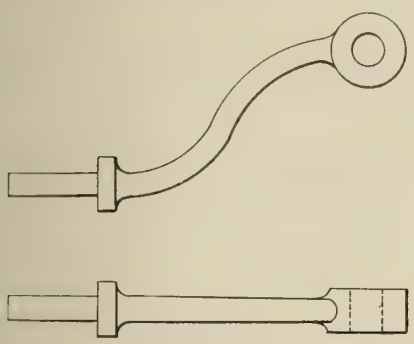

Fig. 20—Forge Practice.

knocked off with a hand hammer immediately the forging is taken from the die. In these cases, provision is often made to reduce the thickness of the fin next the forging. This is accomplished in one of two ways; either by imparting the shape seen at A in Fig. 17, or that at B. In either case, ample room is left to the fin to be squeezed out, while around its zone of attachment, it is extremely thin.

Removal of Forgings from the Dies.

Another thing to be noticed is getting the forgings out of the dies. In Fig. 12 the bar, from which the valve stems are forged in succession, forms a porter bar by which the forgings are manipulated and rotated. Fig. 13 shows a similar case. In Fig. 14 a porter is welded on the lump immediately before it is put into the die, a groove being provided for the bar to lie in. In Figs. 15 and 17 no provision is made, but the forgings are easily lifted out by prying under the fin which forms. Sometimes kickers are fitted under the die which knock out the forging from below, the kicker being operated by striking a lever with a hammer, or by a pedal, or in some cases with an hydraulic cylinder.

Figs. 18 and 19 illustrate the making of a forging in two dies under adjacent hammers. In the first Fig., the forging shown at A, is roughed into a solid globular form at 1, and the stem roughed down in the groove 2, adjacent on the dies, one half of which is seen in plan. In the second figure, the eye is finished in 3, the stem in 4, and the bar cut off at 5.

Bent or Curved Outline Work.

A considerable volume of work is of bent or curved outline in the longitudinal direction. This may or may not be stamped, thus, in the dies. In the engineers' smithy and in heavy forgings the bending is more conveniently done at a second stage. For example, in Fig. 20, the upper and second figure illustrate a bent forging as made at one operation. The lower figure shows it as made straight to be bent afterwards. A block would be provided on which to bend it. Fig. 21 is another familiar article which is made by either method. If these are done at one heat a rough preliminary bending is desirable in order to avoid much waste of material and much fin. These are examples of rather lumpy pieces. Forgings which are bent in plate and bar come under another grouping to be dealt with in the next article.

Only when very considerable differences exist between adjacent sections is the practice of reduction or drawing-down departed from. This occurs in consequence either of great differences in sections or in lengths. Large bosses on small webs are representative of the first and bosses and eyes on long rods are typical of the second. In examples of the first kind, the bosses are frequently welded to the web in preference to drawing-down. In the second class, a short portion of rod or web is drawn down from the boss, the rod portion being scarfed and welded to the main rod.

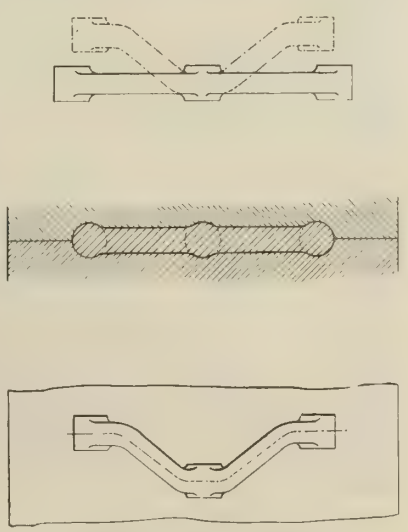

Fig. 21—Forge Practice.

AN OIL FUEL LOCOMOTIVE.

The first locomotive in Scotland to be fitted with oil fuel apparatus has just been put in service by the Caledonian Railway. The engine has an ordinary coal tender, but on the top of the tender there has been placed a tank having a capacity for 520 gallons of oil, from which a pipe is led to the furnace. The pipe branches out to either side, and allows the oil to enter through two injectors placed 18 in. apart. From these injectors the oil is sprayed into the furnace by steam, and is spread over the bars, and over a small quantity of coal which is required to facilitate combustion and to keep a fire in the furnace when the oil supply is turned off.

The oil feed is regulated by a controlling valve on each of the injectors, and the fire box is specially protected in order to withstand the intense heat. When drawing only the tender and one saloon carriage the fuel consumption is 1 1-2 lbs. per mile, and when drawing a full train it is 27 lbs. per mile. The present supply tank is sufficient for a run of 140 miles.

THE CANADIAN GENERAL ELECTRIC CO.

The Canadian General Electric Co., who at present occupy the building at the corner of St. Sacrament and St. Peter streets, Montreal, have purchased an extensive property on the south side of St. Antoine street, opposite the new Canadian Pacific Windsor street station, upon which they will commence this spring the erection of a handsome office and warehouse building to be used exclusively by the Canadian General Electric Co. and the Canada Foundry Co., Ltd. The building, which has been designed by Messrs. Ross & McFarlane, architects, Montreal, will be a handsome structure of cut stone and brick, consisting of five storeys and basement. The offices, showrooms, and warehouse floors will be equipped with every modern device for facilitating dispatch of business, and will afford ample space for the company's rapidly increasing trade.

The Canadian General Electric Co. have within the last two or three years either purchased or erected suitable buildings for their requirements in Halifax, Toronto, Winnipeg and Vancouver, and the erection of the Montreal building is in pursuance of their policy to provide every possible facility for taking care of the growth of business.

Railways are the great purchasers of materials of many kinds, and the moment they are forced to stop buying the effect begins to be felt in the forest, the mine, the mill and the factory.

The Chain Drive as a Power Transmission Medium

By C. T. R.

The contents of this article tell of the increasing popularity of the Chain Drive over a wide field of application and indicate that while its adaptability may be in numerous circumstances limited, there is, nevertheless, with the continued improvements being developed in design and quality of material, a strong possibility of its scope being still further extended.

ALTHOUGH the question of power transmission is only one of many to which the engineer has to give his attention, yet in these days of great and increasing activity, it comes about that none of us can afford to be indifferent to any factor which makes for better, quicker or cheaper production. Plants, factories and mills are extending in every direction as the supply falls short of the demand, and it is the engineer with the knowledge of where to save, who is mainly responsible for these extensions. That chain driving, which has many advantages over other methods of power transmission in many cases is a factor of considerable importance, is evidenced by the fact that in every part of the world engineers are using this drive to a large extent.

Record of Chain Drive Output.

Recent enquiry from the Canadian representatives of the originators and pioneers of chain driving, Hans Renold, Ltd., Manchester, England, elicited the information that this firm's output during the last five years, for chain drives for strictly engineering use was as follows:—

	H.P.
1907	30,500
1908	43,000
1909	48,100
1910	67,360
1911	99,600

Particulars of Installations.

The field of application for chain driving is unlimited. In Great Britain, drives ranging in size from ⅛ to 500 h.p. may be found doing duty under all sorts of conditions from the dish-washing machine in a provincial hotel, to the main shafts of mammoth steel rolling mills. Chain drives have been in operation with great success in the South African gold mines since the stamps first dropped, and one new textile plant in India has just placed an order for chain driving equipment valued at $30,000.

Canada has perhaps adopted chain driving more generally than other countries, as, of course, her development has taken place during the last decade. From Newfoundland to the lumber mills of the Pacific coast, from the hydro-electric stations at the Niagara Falls and the paper mills of the Soo to the Saguenay district and the mines of Northern Ontario, chain drives—which have proved their high efficiency and great durability under what were in many cases new and severe conditions—may be found. Nor does one find the chain drive used in isolated cases only. The experimental stage has long since passed, else one would not see such complete installations as that of the Wayagamack Pulp & Paper Company, who in their new mills at Three Rivers used over 40 Renold Chain Drives transmitting from 5 h.p. to 100 h.p.

One of the most interesting of the many complete installations of chain drives in this country is that of a prominent eastern firm who, having to increase their plant, duplicated the existing six-storey building, using similar equipment throughout the new addition, with the exception that the power was transmitted from one motor by means of chains to the different floors instead of by belt and ropes as formerly. Needless to say such a departure from old and tried methods was not made without the engineers studying carefully the advantages of chain driving generally.

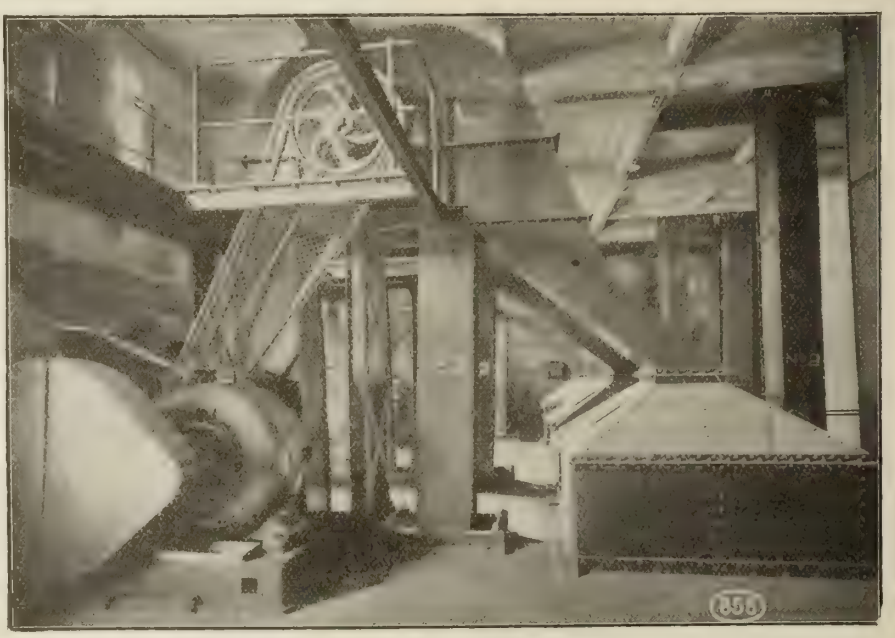
Summary of Design and Application.

Space does not permit us to discuss the design of chains and their various applications, but it might be well to summarize some of the advantages:

(1)—It is positive, inasmuch as the chain cannot slip in the wheels. It is elastic, inasmuch as the weight of the chain which hangs between the wheels may act as a spring; the lubricant in the bearings and in certain cases even the shapes of the links adding to this quality. The effect of this elasticity is to considerably reduce the vibration and noise which is inseparable from such a positive power transmission as spur gearing, while the positive nature of the chain drive has in many cases increased the production of machines from 15 to 30 per cent.

(2)—Chain driving is highly efficient; experiments having shown that the efficiency of a well-designed chain drive is somewhere between 97-98½ per cent. Also, the nature of the action of the chain upon the wheels is such that this high efficiency is maintained throughout the life of the drive and is not seriously affected by minute inaccuracies of erection, as is the case with some forms of tooth gearing.

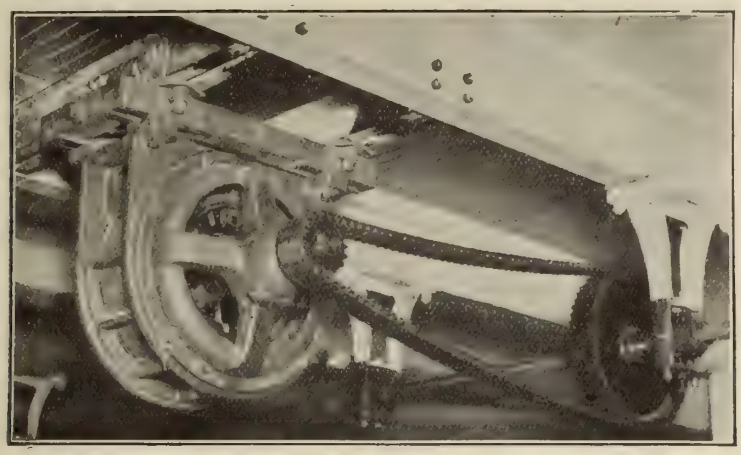
(3)—As compared with rope or belt, the centre distance for chain driving never exceeds 8 feet or 9 feet and can, if circumstances require, be made so small that the chain wheels barely clear one another. For this reason it is even possible to take out a pair of spur wheels, replace them by chain wheels of smaller diameter and get, as the result,



One of eight drives forming part of an installation of over forty Renold Chain drives in a grain elevator in Great Britain.

a highly satisfactory drive as regards efficiency and absence of noise and vibration.

Partly on account of the above advantages, and partly because it is not necessary that there should be any greater initial tension in the chain than such as is caused by its own weight, there are very heavy incidental economies, effected by chain driving. The absence of tension results both in saving of power and in reduction of wear and tear of bearings, shafting and machine parts. In conclusion, we believe that chain driving —which must be classified among the prominent methods of power transmission for strictly engineering purposes— will continue to grow in popularity, and in fact, become recognized as a standard system.



One of five 35 H.P. Renold Chain drives installed by Jones & Glassco, Montreal, in a prominent new Montreal plant.

Layout and Equipment of the Blacksmiths Shop

By Frank Walker

The writer will be remembered as having contributed to our columns recently, a paper on "Hardening and Tempering Carbon Steel Tools," and the widespread appreciation brought to our notice then, will, we are sure be once more evident in the present instance. The requirements of the Blacksmiths' Department are treated in the following pages in a thoroughly practical manner, and show in every detail, a familiarity with and intimate grasp of the subject.

IT has often struck the writer that the blacksmith's department, especially in small engineering establishments, does not receive that amount of consideration and attention to which the work justly entitles it. The blacksmith's art is indispensable to every industry and many of the professions, and his work, even under the most favorable circumstances, is performed under conditions which obtain in no other trade or handicraft. His material must be heated before it can be worked into shape, and, therefore, must be held and turned by means of tongs. The duration of the heat limits the time at his disposal in which to effect the operation in view, and while the work is heating he must think out his plan of action, so that the greatest amount of work may be done while the heat lasts. Under these conditions, it is surely false economy to handicap him still further by an ill-arranged and badly lighted working place, and a scarcity of efficient tools. The blacksmith is practically the only mechanic who makes his own tools, and too often insufficient time is allowed him either to make new tools or repair the old ones.

The advent of steel and malleable cast iron has no doubt greatly simplified his work, as many intricate machine parts which were formerly forged are now cast in one or other of these materials, but it still remains that the blacksmith's trade is the most important of those involved in engineering construction and maintenance. The forge equipment and its arrangement, for an expeditious and economic output, should be, in the writer's opinion, as shown and described in the following article.

Shop Lay-out.

The first thing to be considered is the amount of space required for each forge. This will depend, of course, very much upon the class of work to be done, but it is, in all cases, necessary to have sufficient head-room to insure good ventilation and an abundance of light. The height should never be less than 16 feet, and, if heavy work is contemplated, this may be increased with advantage by 4 or 5 feet more. Windows of liberal size must also be provided. Should two or more forges be required, by far the best arrangement for general work is to place them in a row along the wall of the shop at a distance of 4 feet, measured from the wall to the nozzle of the tuyere, and 16 feet apart centre to centre, with a window between each pair.

The anvil should be placed 6 feet from the tuyere and 5 feet from the centre line of the forge, in such a position that the blacksmith turns to the right to place the heated work upon it. The beckhorn of the anvil should point to his left. The space for the helper at the back of the anvil should be not less than 10 feet wide, and in large shops where the forges are situated on either side, the space between the rows of anvils should not be less than 25 feet, with the steam-hammers and other general tools ranged up the centre.
